LINEAR–Operational Amplifiers-Characteristics

Single Units

In this list the "Comp." column indicates the number of compensation components required at unity gain. Thus 0 indicates a fully compensated amplifier. The bandwidth and slew rate are listed with the amplifier compensated for unity gain.

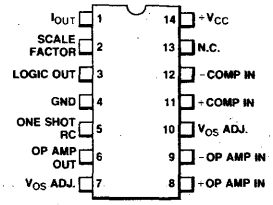
VOLTAGE-TO-FREQUENCY CONVERTER

FAIRCHILD LINEAR INTEGRATED CIRCUITS

DESCRIPTION – The μA4151 is a monolithic building block used to convert dc voltage to digital pulses. The frequency of the output pulses is proportional to the dc input voltage.

The μA4151 consists of a voltage comparator, a monostable multivibrator and a precision switched current source (see block diagram).

The μA7151 is the same device as the μA4151 with a high performance operational amplifier on the same chip. The single supply op amp conditions the input signal and provides a significant improvement in system performance.



- **SINGLE SUPPLY (+8 V_{DC} TO +30 V_{DC})**
- **LINEARITY TO ±0.5%**
- **PROGRAMMABLE SCALE FACTOR**
- **PULSE OUTPUT COMPATIBLE WITH ANY LOGIC FORM**
- **TEMPERATURE STABILITY TYPICALLY ±100 ppm/°C**
- **HIGH NOISE REJECTION**
- **EASILY TRANSMITTABLE OUTPUT**
- **SIMPLE FULL-SCALE TRIM**
- **SINGLE-ENDED INPUT, REFERENCED TO GROUND**
- **ALSO PROVIDES FREQUENCY-TO-VOLTAGE CONVERSION**
- **HIGH PERFORMANCE OP AMP INCLUDED IN μA7151**

CIRCUIT DESCRIPTION

The μA7151 consists of five circuit blocks as shown in Figure 1. The blocks may be connected in a variety of ways to construct voltage-to-frequency converters (VFC), frequency-to-voltage converters (FVC), or other circuit functions. The circuit blocks are:

1. A differential input comparator featuring very high gain, low offsets, and a common mode range which includes ground.
2. A one-shot multivibrator with the time constant set by an external RC (T = 1.1RC) connected to the RC terminal, triggered by the output of the comparator being high.
3. A precision switched current source that is turned on to the value of I_{REF} when the one-shot is on and goes to zero when the one-shot is off. The current I_{REF} is set by an external R_S, connected from the scale factor terminal-to-ground and is equal to the reference voltage divided by R_S and is optimized when set to 138 μA.
4. An open collector output that provides a buffered output from the one-shot.
5. An operational amplifier whose common mode range includes ground and has offset null capability. The op amp has high gain, low offset voltage, low input currents, good PSRR and CMRR, and low drift.

PRINCIPLE OF OPERATION

Voltage to Frequency Conversion (VFC)

As a voltage to frequency converter the μA7151/4151 can be connected in several configurations depending on the input voltage, required accuracy, and response time. In all the applications we will see that the input voltage is converted to a current and the circuit will turn the switched current source on at the rate necessary so that the average current from the current source is equal to the input current. As the input voltage (and current) increases, the current source must turn on more often, and the output frequency increases.

SELECTING COMPONENTS FOR THE VFC

Voltage-to-frequency converters can be used for full scale voltages of 100 mV or greater and full scale frequencies of 1 Hz to 100 Hz. Input voltages in excess of $V_{CC}+$ can be accomodated with appropriate resistor dividers to attenuate the voltages. The following components selection guidelines should be used.

1. R_S should be approximately 14 kΩ to optimize the system performance versus temperature. R_S is normally a 12 kΩ fixed resistor and a 5 kΩ pot to be used to adjust the full scale output frequency. Small variations in R_S have minimal effect on system temperature performance. $I_{REF} = V_{REF}/R_S = 1.95\ V/R_S$
2. $R_0\ C_0$ sets the one-shot pulse width, $T_0 = 1.1\ R_0\ C_0$. This pulse width must be shorter than the minimum period of the maximum frequency ie, set it equal to .75 $(1/f_0)$. Therefore, $R_0\ C_0 = .68\ (1/f_0)$. Values of R_0 should be between 6.8 kΩ and 680 kΩ and C_0 should be from .001 μF to 1 μF.
3. R_B should be as low as possible for the highest accuracy, (this reduces the effect of current source R_{OUT}) but must be large enough to insure that the current source output is greater than $V_{IN}\ max/R_B$. Therefore, choose R_B such that $R_B \sim 1.33\ V_{IN}\ max/I_0$.
4. C_B for Figure 2 must be chosen to trade-off between accuracy and response time. Larger values of C_B give greater system accuracy but response time is limited by the $R_B\ D_B$ time constant. A good choice for D_B is $10^{-2}/f_0$.
5. C_1 for Figures 3 and 4 can be selected depending on the output frequency. The smaller C_1 is the faster the system response wil be. C_1 must be large enough to limit the amplifier swing. The op amp will swing a voltage set by I_0T_0/C_1, so if the comparator is biased at 2/3 $V_{CC}+$ this constrains $C_1 > 3\ I_0T_0/2\ V_{CC}+$. A nominal value of $C_1 = 5 \times 10^{-5}/f_0$ meets this requirement.

COMPARISON OF VOLTAGE TO FREQUENCY CIRCUITS

Table I shows a comparison of the three basic circuits set-up for a 0 to 10 V input range and a full scale output of 10 kHz.

FREQUENCY TO VOLTAGE CONVERSION

The μA7151/4151 can be connected as frequency-to-voltage converter (FVC). This circuit basically works by putting out a current pulse per cycle of input frequency and intergrating the current pulses across an output resistor to give an output voltage which is proportional to the average value of I_0 $(I_0T_0f_{IN})$.

μA78S40
UNIVERSAL SWITCHING REGULATOR SUBSYSTEM

DESCRIPTION: The uA78S40 is a Monolithic Regulator Subsystem consisting of all the active building blocks necessary for switching regulator systems. The device consists of a temperature compensated voltage reference, a duty cycle controllable oscillator with an active current limit circuit, an error amplifier, high current, high voltage output switch, a power diode and an uncommitted operational amplifier. The device can drive external npn or pnp transistors when currents in excess of 1.5 A or voltages in excess of 40 V are required. The device can be used for step down, step up or inverting switching regulators as well as for series pass regulators. It features wide supply voltage range, low standby power dissipation, high efficiency and low drift. It is useful for any stand alone, low part count switching system and works extremely well in battery operated systems.

- **STEP UP, STEP DOWN OR INVERTING SWITCHING REGULATORS**
- **OUTPUT ADJUSTABLE FROM 1.3 to 40 V**
- **OUTPUT CURRENTS TO 1.5 A WITHOUT EXTERNAL TRANSISTORS**
- **OPERATION FROM 2.5 TO 40 V INPUT**
- **LOW STANDBY CURRENT DRAIN**
- **80 dB LINE AND LOAD REGULATION**
- **HIGH GAIN, HIGH CURRENT, INDEPENDENT OP-AMP**

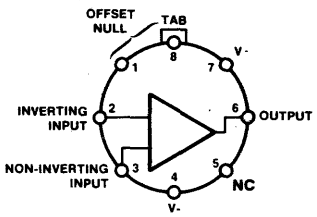
μA714



PRECISION OPERATIONAL AMPLIFIER

FAIRCHILD LINEAR INTEGRATED CIRCUITS

DESCRIPTION – The μA714 is a Monolithic Instrumentation Operational Amplifier constructed using the Fairchild Planar* epitaxial process. It is intended for precise, low level signal amplification applications where low noise, low drift and accurate closed loop gain are required. The offset null capability, low power consumption, very high voltage gain as well as wide power supply voltage range provide superior performance for a wide range of instrumentation applications.

- **LOW INPUT NOISE CURRENT... 0.17 pA/√Hz @1.0 kHz max**
- **HIGH OPEN LOOP GAIN... 500,000 typically**
- **LOW INPUT OFFSET CURRENT... 2.8 nA max for μA714**
- **LOW INPUT VOLTAGE DRIFT... 0.6 μV/°C for μA714A**
- **HIGH COMMON MODE REJECTION... 100 dB min for μA714 and 714A**
- **WIDE POWER SUPPLY RANGE... ±22V**
- **OFFSET NULL CAPABILITY.**

Slewing Rate	$R_L \geq$ 2.0 kΩ		0.25		V/μsec
Closed Loop Bandwidth	A_{VCL} = +1.0		1.2		MHz
Open Loop Output Resistance	V_O =0, I_O = 0		60		Ω
Power Consumption	V_S = ±3.0 V		75 4.0	120 6.0	mW
Offset Adjustment Range	R_P = 20 kΩ		±4.0		mV
The following specifications apply for V_S = ±15 V, −55°C ≤ T_A ≤ +125°C, unless otherwise noted.					
Input Offset Voltage	Note 1		60	200	μV
Average Input Offset Voltage Drift Without External Trim With External Trim	R_P = 20 kΩ		 0.3 0.3	 1.3 1.3	 μV/°C μV/°C
Input Offset Current			1.2	5.6	nA
Average Input Offset Current Drift			8.0	50	pA/°C
Input Bias Current			±2.0	±6.0	nA
Average Input Bias Current Drift			13	50	pA/°C
Input Voltage Range		±13.0	±13.5		V
Common Mode Rejection Ratio	V_{CM} = ± CMVR	106	123		dB
Power Supply Rejection Ratio	V_S = ±3.0 V to ±18 V	94	106		dB
Large Signal Voltage Gain	$R_L \geq$ 2.0 kΩ, V_O = −10 V to +10 V	150	400		V/mV
Maximum Output Voltage Swing	$R_L \geq$ 2.0 kΩ	±12.0	±12.6		V

NOTES:
1. Input offset voltage measurements are performed by automated test equipment approximately 0.5 seconds after application of power.
2. For supply voltage less than ±22 volts, the absolute maximum input voltage is equal to the supply voltage.
3. Parameter is not 100% tested; 90% of units meet this specification.

μA78C00 SERIES

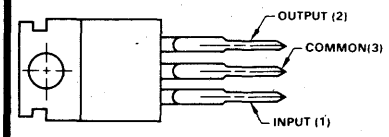
3-TERMINAL POSITIVE VOLTAGE REGULATORS

FAIRCHILD LINEAR INTEGRATED CIRCUITS

GENERAL DESCRIPTION – The μA78C00 series of 3-Terminal Positive Voltage Regulators is constructed using the Fairchild Planar* epitaxial process. This series is designed to meet the special environmental reliability and low drift requirements for high volume cost effective product applications. On card regulation eliminates the distribution problems associated with a central power supply. The 3-terminal IC voltage regulators employ internal current limiting, thermal shutdown and safe area compensation that make these IC voltage regulators virtually indestructable. The 78C00 provides improved line and load regulation as well as high ripple rejection. The performance standards meet all Domestic, Continental and Far East consumer product electrical standards.

The fixed voltage series designated 78C00 is available in 12 options from 8-24 V and is capable of delivering 500 mA.

A 0.33 μF decoupling capacitor should be used at the input pin. A 0.1 μF capacitor at the output pin will improve the transient response.



- **OUTPUT CURRENT IN EXCESS OF 0.5 A**
- **EXCELLENT TRANSIENT RESPONSE**
- **1/2% LOAD AND LINE REGULATION**
- **MAX DROPOUT VOLTAGE 2.5 V**
- **NO EXTERNAL COMPONENTS REQUIRED**
- **OUTPUT TRANSISTOR SAFE AREA PROTECTION**
- **INTERNAL SHORT CIRCUIT CURRENT LIMIT**
- **LOW OUTPUT IMPEDANCE**

ABSOLUTE MAXIMUM RATINGS

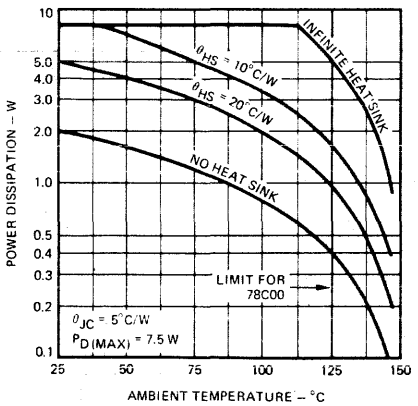
DESIGN CONSIDERATIONS

The μA78C00 fixed voltage regulator series has thermal overload protection from excessive power, internal short circuit protection which limits the circuit's maximum current, and output transistor safe area compensation for reducing the output short circuit current as the voltage across the pass transistor is increased.

Although the internal power dissipation is limited, the junction temperature must be kept below the maximum specified temperature (125°C) in order to meet data sheet specifications. To calculate the maximum junction temperature or heat sink required, the following thermal resistance values should be used:

PACKAGE	TYP θ_{JC}	MAX θ_{JC}	TYP θ_{JA}	MAX θ_{JA}
Power Watt	4.0	7.0	75	80

$$P_{D(MAX)} = \frac{T_{J(MAX)} - T_A}{\theta_{JC} + \theta_{CA}} \text{ or } \frac{T_{J(MAX)} - T_A}{\theta_{JA}} \text{ (Without a heat sink)}$$



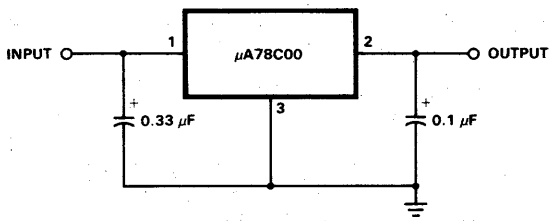
$$\theta_{CA} = \theta_{CS} + \theta_{SA}$$

Solving for T_J: $T_J = T_A + P_D (\theta_{JC} + \theta_{CA})$ or $T_A + P_D \theta_{JA}$ (Without heat sink)

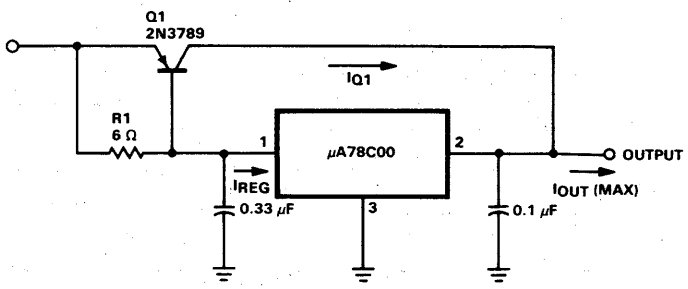
Where:

T_J = Junction Temperature
T_A = Ambient Temperature
P_D = Power Dissipation
θ_{JA} = Junction to ambient thermal resistance
θ_{JC} = Junction to case thermal resistance
θ_{CA} = Case to ambient thermal resistance
θ_{CS} = Case to heat sink resistance
θ_{SA} = Heat sink to ambient thermal resistance

WORST CASE POWER DISSIPATION VERSUS AMBIENT TEMPERATURE



©IC MASTER 1978



TYPICAL APPLICATIONS

In many μA78C00 applications, compensation capacitors may not be required. However, for stable operation of the regulator over all input voltage and output current ranges, bypassing of the input and output (0.33 μF and 0.1 μF, respectfully) is recommended. Input bypassing is necessary if the regulator is located far from the filter capacitor of the power supply. Bypassing the output will improve the transient response of the regulator.

μA78C00 FIXED VOLTAGE VOLTAGE REGULATOR

Figure 1 shows the equivalent circuit of the μA78C00 regulator. The reference is derived from Zener diode D1 and compensated by the base-emitter voltage of the error amplifier Q4. Additional gain is provided by Q7 and Q8 to the Darlington-connected emitter-follower output stage of Q10 and Q11. The output stage is compensated by capacitor C1. A positive start-up condition is ensured by FET transistor Q1 to provide base current to transistors Q2 and Q5. Q2, Q5 and Q6 then form a positive feedback loop which raises the base voltage of Q2 until the reference Zener D1 conducts. Thermal overload protection is achieved by transistor Q3. The bias to the base-emitter voltage of Q3 is derived from D1 via Q2 and the divider network of R1 and R2. At high junction temperatures, Q3 turns on and removes the drive to the output stage. Current-limit transistor Q9 protects the device against accidental shorts by sensing the voltage drop across R7 while Zener diode D2 along with Q9 and resistors R5, R6 and R7 limit the power dissipation to a safe value.

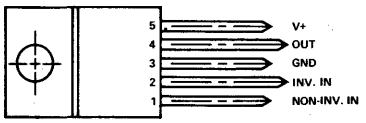
TDA2002 • TDA2002A

8 WATT AUDIO POWER AMPLIFIERS

FAIRCHILD LINEAR INTEGRATED CIRCUITS



GENERAL DESCRIPTION – The TDA2002 and TDA2002A are monolithic integrated circuits designed for class B audio power amplifier applications using low impedance loads (down to 1.6 Ω). They are constructed using the Fairchild Planar* epitaxial process. The devices typically provide 8 W at 14.4 V, 2 Ω and 6.5 W at 16 V, 4 Ω.

The TDA2002 and TDA2002A are provided in a 5-pin power package, with two pin configurations (H and V) for ease in mounting either horizontally or vertically in the PC board.

The TDA2002A is the same electrically as the TDA2002 except it does not include the overvoltage (Load dump) protection circuit.

- **THERMAL SHUT DOWN**
- **SHORT CIRCUIT PROTECTION**
- **OVERVOLTAGE PROTECTION (TDA2002)**
- **LOW EXTERNAL COMPONENTS**
- **HIGH CURRENT CAPABILITY (3.5 A)**
- **MINIMUM SPACE REQUIREMENT**
- **WIDE SUPPLY VOLTAGE RANGE (8 V to 18 V)**

DESIGN CONSIDERATIONS

The board layout of the TDA2002 and TDA2002A is critical to assure good stability. The layout shown in Figure 20 is recommended. If a different layout is used, it is important that the ground points of inputs 1 and 2 be well decoupled from the ground of the output. Pin lengths should be as short as possible.

The component values shown on the applications schematics are recommended. However, other values may be used, and Table 1 is intended to serve as a guide for the designer on the effect of changing component values.

No electrical insulation is needed between the package tab and the heat sink, if the heat sink is electrically isolated or is at ground potential.

Component	Recommended value	Purpose	Larger than recommended value	Smaller than recommended value
C1	10 μF	Input DC decoupling		Noise at switch-on, switch-off
C2	470 μF	Ripple rejection		Degradation of PSRR
C3	0.1 μF	Supply bypassing		Danger of oscillation
C4	1000 μF	Output coupling to load		Higher low frequency cutoff
C5	0.1 μF	Frequency stability		Danger of oscillation at high frequencies with inductive loads
CF_B	$\simeq \frac{1}{2\pi B R 1}$	Upper frequency cutoff	Lower bandwidth	Larger bandwidth
R1	$(A_V - 1) \cdot R2$	Closed loop gain determination		Increase of drain current
R2	2.2 Ω	Closed loop gain and PSRR determination	Degradation of PSRR	
R3	1 Ω	Frequency stability	Danger of oscillation at high frequencies with inductive loads	
R_{FB}	$\cong$ 20 R2	Upper frequency cutoff	Poor high frequency attenuation	Danger of oscillation

APPLICATIONS INFORMATION:

Several typical applications of the TDA2002 and TDA2002A are shown in this section, together with printed circuit board layouts.

Figures 19 and 20 show a typical circuit with CFB, RFB shown dashed. CFB and RFB may be used to adjust the bandwidth after the gain has been set by the ratio R1/R2. (See Figure 15).

Figures 23 and 24 show a typical 15 watt bridge circuit utilizing two devices. A potentiometer (P1) is included to balance the offset voltages between the two devices.

THERMAL SHUTDOWN

Both the TDA2002 and TDA2002A have been designed with a thermal shutdown feature. Typical curves of output power and supply current as a function of case temperature are shown in Figures 17 and 18. The thermal overload circuit reduces the drive to the output stage when the junction temperature exceeds the design threshold. The result is a reduced supply current and power output consistent with maintaining the junction temperature at the design limit.

The thermal overload feature offers several important advantages to the circuit designer:

1. The device can withstand excessive ambient temperatures (below 150° C) and temporary or permanent overloads on the output.
2. The safety margin on the heat sink design may be reduced because the device will not be damaged by excessive junction temperature (below 150° C). The only result of this increased junction temperature will be a reduction in output power and supply current.

OVERVOLTAGE (LOAD DUMP) PROTECTION

The TDA2002 has been designed with a built-in circuit which enables this device to withstand a series of voltage spikes (see Figure 25). The load dump feature starts at about 18 V, so the operating voltage must not exceed 18 V.

This feature is particularly important in automobile applications, and the pulse train shown in Figure 25 is intended to simulate the voltage spikes which often occur on the supply line in automotive applications.

If the supply voltage peaks exceed 40 V, then an LC network must be inserted between the supply and Pin 5 to assure that the pulses at Pin 5 will not exceed the limits shown in Figure 25. A typical LC network is shown in Figure 26. With this network a train of pulses up to 120 V and 2 ms wide can be applied from the supply line.

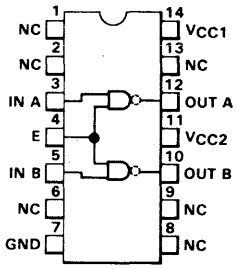
DUAL TTL TO MOS DRIVER

FAIRCHILD LINEAR INTEGRATED CIRCUITS

GENERAL DESCRIPTION – The 9643 and 9644 are dual positive logic "AND" and "NAND" TTL-to-MOS drivers respectively. The 9643 DC/PC is a functional replacement of the SN75322 with one important exception: the two external PNP transistors are no longer needed for operation. The 9643 DC/PC is also a functional replacement for the 75363 with the important exception that the V_{CC3} supply is not needed. The 9644 is a logical inversion of the 9643 and is a functional replacement for the 75361. The pin connections normally used for the external PNP transistors are purposely not internally connected to the 9643 DC/PC.



Both devices have separate driver address inputs with common strobe. Both devices accept standard TTL and DTL input signals and provide high-current and high-voltage output levels suitable for driving MOS circuits. The 9643 may be used to drive the chip-enable clock of the TMS4030 MOS RAM. The 9644 is suitable for driving both clock and address inputs for the TMS4062 and 1103 RAM. The 9643 and 9644 operate from the TTL 5 V supply and the MOS supply.

The 9643A and 9644A are high voltage versions of the 9643 and 9644. The "A" version is capable of withstanding V_{CC2} voltages up to 18 V_{DC} max.

The 9643A and 9644A are available in 8-pin DIPs for increased board efficiency.

- **DUAL POSITIVE-LOGIC TTL-TO-MOS DRIVERS**
- **VERSATILE INTERFACE CIRCUIT FOR USE BETWEEN TTL AND HIGH-CURRENT, HIGH-VOLTAGE SYSTEMS**
- **OPERATES FROM STANDARD BIPOLAR AND MOS SUPPLY VOLTAGES**
- **HIGH SPEED SWITCHING**
- **TTL AND DTL COMPATIBLE INPUTS**
- **SEPARATE DRIVER ADDRESS INPUTS WITH COMMON STROBE**
- **V_{OH} AND V_{OL} COMPATIBLE WITH POPULAR MOS RAMs**
- **DOES NOT REQUIRE EXTERNAL PNP TRANSISTORS OR V_{CC3}**
- **V_{OH} MINIMUM IS V_{CC2} – 0.5 V**

HA-909/911

Wideband, Low Noise, Operational Amplifiers

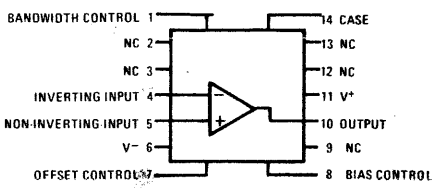
FEATURES

- LOW BROADBAND NOISE — 1μV R.M.S.
- LOW NOISE VOLTAGE — $7nV/\sqrt{Hz}$
- LOW OFFSET VOLTAGE — 2mV
- WIDE BANDWIDTH — 7MHz
- POWER BANDWIDTH — 20kHz
- SUPPLY RANGE — ±5V TO ±20V
- INTERNALLY COMPENSATED

APPLICATIONS

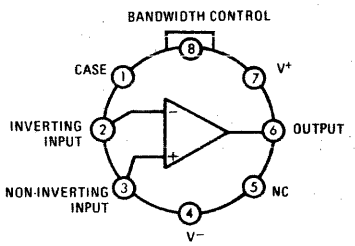
- HIGH Q, WIDEBAND FILTERS
- AUDIO AMPLIFIERS
- SIGNAL GENERATORS

DESCRIPTION



HA-909 and HA-911 are monolithic ampliifers delivering very low noise and excellent bandwidth specifications without the need for external compensation. Additional features of these dielectrically isolated devices include low offset voltage, offset trim capabitlity (14-pin flat package only), and high output current drive capabitlity.

With 7MHz bandwidth and internal compensation these amplifiers are extremely useful in many active filter designs. In audio circuitry requiring quiet operation these devices offer 1 μ V typical broadband noise (10Hz to 1kHz) and 20kHz power bandwidth. 2mV typical offset voltage, offset trim capability, and 20mA output current drive capability (±10.0V swing) make these amplifiers useful in signal conditioning circuits.



HA-909 and HA-911 are available in metal can (TO-99) and 14-pin flat packages. HA-909 is specified over the -55°C to +125°C range. HA-911 is specified from 0°C to +75°C.

FREQUENCY RESPONSE FOR VARIOUS CLOSED-LOOP GAINS

OUTPUT VOLTAGE SWING VS. FREQUENCY

OPEN LOOP FREQUENCY RESPONSE

DEFINITIONS

INPUT OFFSET VOLTAGE – That voltage which must be applied between the input terminals through two equal resistances to force the output voltage to zero.

INPUT OFFSET CURRENT – The difference in the currents into the two input terminals when the output is at zero voltage.

INPUT BIAS CURRENT – The average of the currents flowing into the input terminals when the output is at zero voltage.

INPUT COMMON MODE VOLTAGE – The average referred to ground of the voltages at the two input terminals.

COMMON MODE RANGE – The range of voltages which is exceeded at either input terminal will cause the amplifier to cease operating.

COMMON MODE REJECTION RATIO – The ratio of a specified range of input common mode voltage to the peak-to-peak change in input offset voltage over this range.

OUTPUT VOLTAGE SWING – The peak symmetrical output voltage swing, referred to ground, that can be obtained without clipping.

INPUT RESISTANCE – The ratio of the change in input voltage to the change in input current.

OUTPUT RESISTANCE – The ratio of the change in output voltage to the change in output current.

POSITIVE OUTPUT VOLTAGE SWING – The peak positive output voltage swing, referred to ground, that can be obtained without clipping.

NEGATIVE OUTPUT VOLTAGE SWING – The peak negative output voltage swing, referred to ground, that can be obtained without clipping.

VOLTAGE GAIN – The ratio of the change in output voltage to the change in input voltage producing it.

BANDWIDTH – The frequency at which the voltage gain is 3dB below its low frequency value.

UNITY GAIN BANDWIDTH – The frequency at which the voltage gain of the amplifier is unity.

POWER SUPPLY REJECTION RATIO – The ratio of the change in input offset voltage to the change in power supply voltage producing it.

TRANSIENT RESPONSE – The closed loop step function response of the amplifier under small signal conditions.

PHASE MARGIN – $(180^o - (\phi_1 - \phi_2))$ where ϕ_1 is the phase shift at the frequency where the absolute magnitude of gain is unity ϕ_2 is the phase shift at a frequency much lower than the open loop bandwidth.

A DIVISION OF HARRIS CORPORATION

HA-2050/2055/2050A/2055A

High Slew Rate F.E.T. Input Operational Amplifiers

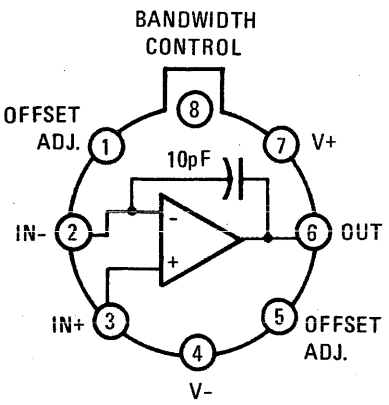
FEATURES

- HIGH SLEW RATE — 120V/μs
- FAST SETTLING — 400ns
- WIDE POWER BANDWIDTH — 2MHz
- HIGH GAIN BANDWIDTH — 20MHz
- HIGH INPUT IMPEDANCE — 10^{12} OHMS
- LOW BIAS CURRENT — 1pA
- TRUE OP AMP – CAN BE OPERATED INVERTING OR NON-INVERTING

APPLICATIONS

- DATA ACQUISITION
- SIGNAL CONDITIONING
- R.F. AND VIDEO AMPLIFICATION

DESCRIPTION



The HA-2050/2055 is an operational amplifier combining the advantages of very high slew rate and wide bandwidth with ultra-low input current and high input resistance. These devices are ideal for use in sample-and-hold circuits, A/D, D/A and sampled data systems; and for use in wide band R.F. or video systems where wide bandwidth at high output levels is required. The device may be operated inverting or noninverting; and external compensation is required only when operated at closed loop gains less than three. An internal feedback capacitor is provided to cancel phase shift in the feedback loop due to input capacitance.

The HA-2050 is guaranteed for operation from -55°C to +125°C and the HA-2055 is guaranteed from 0°C to +75°C.

HA-2060/2065/ 2060A/2065A

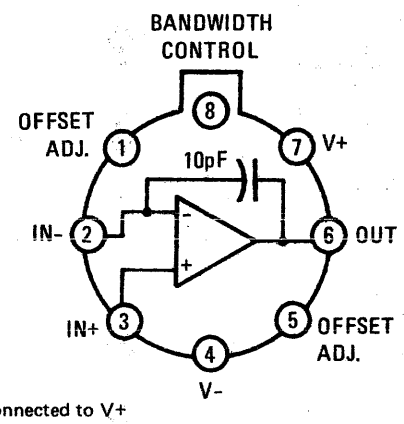
Wide Band F.E.T. Input Operational Amplifier

FEATURES

- GAIN BANDWIDTH PRODUCT — 100MHz
- HIGH INPUT IMPEDANCE — 10^{12} OHMS
- LOW BIAS CURRENT — 1pA
- HIGH SLEW RATE — 35V/μs
- WIDE POWER BANDWIDTH — 600kHz
- TRUE OP AMP – CAN BE OPERATED INVERTING OR NON-INVERTING

APPLICATIONS

- SIGNAL CONDITIONING
- ACTIVE FILTERS
- SIGNAL GENERATORS



DESCRIPTION

The HA-2060/2065 is an operational amplifier combining the advantages of very wide bandwidth and high slew rate with ultra-low input current and high input resistance. These devices are ideal for use in sample-and-hold circuits, active filters, wide band amplifiers, high gain amplifiers with superior bandwidth, and wherever very low closed loop gain and phase shift errors are required. The device may be operated inverting or noninverting; and external compensation is required only when operating at closed loop gains less than five. An internal feedback capacitor is provided to cancel phase shift in the feedback loop due to input capacitance.

The HA-2060 is guaranteed for operation from -55°C to +125°C and the HA-2065 is guaranteed from 0°C to +75°C.

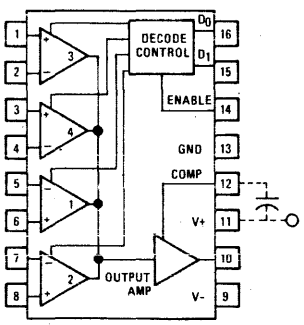
  - SIGNAL SELECTION/MULTIPLEXING
  - OP AMP GAIN
  - OSCILLATOR FREQUENCY
  - FILTER CHARACTERISTICS
  - ADD-SUBTRACT FUNCTIONS
  - INTEGRATOR CHARACTERISTICS
  - COMPARATOR LEVELS

DESCRIPTION

HA-2400/2404/2405 comprise a series of four-channel programmable amplifiers providing a level of versatility unsurpassed by any other monolithic operational amplifier. Versatility is achieved by employing four input amplifier channels, any one (or none) of which may be electronically selected and connected to a single output stage through DTL/TTL compatible address inputs. The device formed by the output and the selected pair of inputs is an op amp which delivers excellent slew rate, gain bandwidth and power bandwidth performance. Other advantageous features for these dielectrically isolated amplifiers include high voltage gain and input impedance coupled with low input offset voltage and offset current. External compensation is not required on this device at closed loop gains greater than 10.



Each channel of the HA-2400/2404/2405 can be controlled and operated with suitable feedback networks in any of the standard op amp configurations. This specialization makes these amplifiers excellent components for multiplexing, signal selection, and mathematical function designs. With 30V/μs slew rate, 40MHz gain bandwidth, and 30M ohms input impedance these devices are ideal building blocks for signal generators, active filters, and data acquisition designs. Programmability coupled with 2mV typical offset voltage and 5nA offset current makes these amplifiers outstanding components for signal conditioning circuits.

HA-2400/2404/2405 are available in a 16 pin dual-in-line package. HA-2400 is specified from -55°C to +125°C. HA-2404 is specified over the -25°C to +85°C range, while HA-2405 operates from 0°C to +75°C.

HA-2500/02/05

Precision High Slew Rate Operational Amplifiers

FEATURES

- HIGH SLEW RATE 30V/μS
- FAST SETTLING 330ns
- WIDE POWER BANDWIDTH 500kHz
- HIGH GAIN BANDWIDTH 12MHz
- HIGH INPUT IMPEDANCE 100MΩ
- LOW OFFSET CURRENT 10nA
- INTERNALLY COMPENSATED

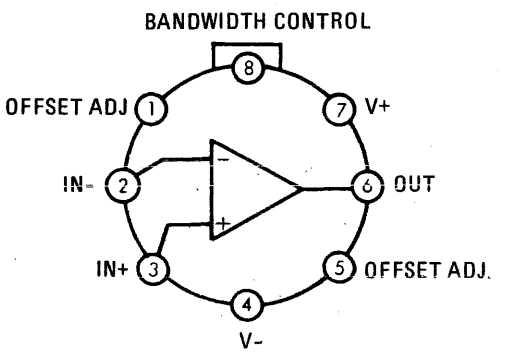
APPLICATIONS

- DATA ACQUISTION SYSTEMS
- R.F. AMPLIFIERS
- VIDEO AMPLIFIERS
- SIGNAL GENERATORS
- PULSE AMPLIFICATION

DESCRIPTION

HA-2500/2502/2505 comprise a series of monolithic operational amplifiers whose designs are optimized to deliver excellent slew rate, bandwidth, and settling time specifications. The outstanding dynamic features of this internally compensated device are complemented with low offset voltage and offset current.

These dielectrically isolated amplifiers are ideally suited for applications such as data acquisition, R.F., video, and pulse conditioning circuits. Slew rate of ±25V/μs and 330ns (0.1%) settling time make these devices excellent components in fast, accurate data acquisition and pulse amplification designs. 12 MHz bandwidth and 500kHz power bandwidth make these devices well suited to R.F. and video applications. With 2mV typical offset voltage plus offset trim capability and 10nA offset current, HA-2500/2502/2505 are particularly useful components in signal conditioning designs.



The gain and offset voltage figures of the HA-2500 series are optimized by internal component value changes while the similar design of the HA-2510 series is maximized for slew rate.

HA-2500/2502/2505 are available in metal can (TO-99) packages. HA-2500 and HA-2502 are specified over the -55°C to +125°C range. HA-2505 is specified from 0°C to +75°C.

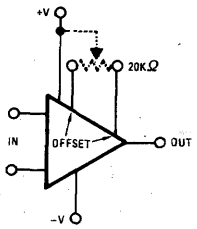
SLEW RATE AND SETTLING TIME



TRANSIENT RESPONSE

SLEW RATE AND TRANSIENT RESPONSE

SUGGESTED OFFSET ZERO ADJUST HOOK-UP

DEFINITIONS

INPUT OFFSET VOLTAGE – That voltage which must be applied between the input terminals through two equal resistances to force the output voltage to zero.

INPUT OFFSET CURRENT – The difference in the currents into the two input terminals when the output is at zero voltage.

INPUT BIAS CURRENT – The average of the currents flowing into the input terminals when the output is at zero voltage.

INPUT COMMON MODE VOLTAGE – The average referred to ground of the voltages at the two input terminals.

COMMON MODE RANGE – The range of voltages which is exceeded at either input terminal will cause the amplifier to cease operating.

TRANSIENT RESPONSE – The closed loop step function response of the amplifier under small signal conditions.

GAIN BANDWIDTH PRODUCT – The product of the gain and the bandwidth at a given gain.

SLEW RATE (Rating Limiting) – The rate at which the output will move between full scale stops, measured in terms of volts per unit time. This limit to an ideal step function response is due to the non-linear behavior in an amplifier due to its limited ability to produce large, rapid changes in output voltage (slewing) . . . restricting it to rates of change of voltage lower than might be predicted by observing the small signal frequency response.

SETTLING TIME – Time required for output waveform to remain within 0.1 percent of final value.

HARRIS SEMICONDUCTOR
A DIVISION OF HARRIS CORPORATION

HA-2510/2512/2515

High Slew Rate Operational Amplifiers

FEATURES

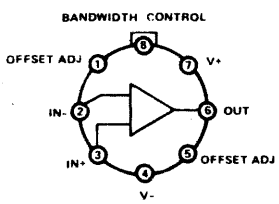
- HIGH SLEW RATE — 60V/μs
- FAST SETTLING — 250ns
- WIDE POWER BANDWIDTH — 1,000kHz
- HIGH GAIN BANDWIDTH — 12MHz
- HIGH INPUT IMPEDANCE — 100MΩ
- LOW OFFSET CURRENT — 10nA
- INTERNALLY COMPENSATED

APPLICATIONS

- DATA ACQUISITION SYSTEMS
- R.F. AMPLIFIERS
- VIDEO AMPLIFIERS
- SIGNAL GENERATORS
- PULSE AMPLIFICATION

DESCRIPTION

The HA-2510/2512/2515 are a series of high performance operational amplifiers which set the standards for maximum slew rate, highest accuracy and widest bandwidth for internally compensated monolithic devices. In addition to excellent dynamic characteristics, these dielectrically isolated amplifiers also offer low offset current and high input impedance.



The ±60V/ μs slew rate and 250ns (0.1%) settling time of these amplifiers is ideally suited for high speed D/A, A/D, and pulse amplification designs. HA-2510/2512/2515's superior 12MHz gain bandwidth and 1000kHz power bandwidth is extremely useful in R.F. and video applications. For accurate signal conditioning these amplifiers also provide 10nA offset current, coupled with 100MΩ input impedance, and offset trim capability.

The HA-2510/2512 are available in metal can (TO-99) and 14-pin flat packages. HA-2510 and HA-2512 are specified from -55°C to +125°C. HA-2515 is specified over the 0°C to +75°C range, and is available in the TO-99 package.

DEFINITIONS

INPUT OFFSET VOLTAGE – That voltage which must be applied between the input terminals through two equal resistances to force the output voltage to zero.

INPUT OFFSET CURRENT – The difference in the currents into the two input terminals when the output is at zero voltage.

INPUT BIAS CURRENT – The average of the currents flowing into the input terminals when the output is at zero voltage.

INPUT COMMON MODE VOLTAGE – The average referred to ground of the voltages at the two input terminals.

COMMON MODE RANGE – The range of voltages which is exceeded at either input terminal will cause the amplifier to cease operating.

COMMON MODE REJECTION RATIO – The ratio of a specified range of input common mode voltage to the peak-to-peak change in input offset voltage over this range.

OUTPUT VOLTAGE SWING – The peak symmetrical output voltage swing, referred to ground, that can be obtained without clipping.

INPUT RESISTANCE – The ratio of the change in input voltage to the change in input current.

OUTPUT RESISTANCE – The ratio of the change in output voltage to the change in output current.

VOLTAGE GAIN – The ratio of the change in output voltage to the change in input voltage producing it.

UNITY GAIN BANDWIDTH – The frequency at which the voltage gain of the amplifier is unity.

HARRIS SEMICONDUCTOR
A DIVISION OF HARRIS CORPORATION

HA-2520/22/25

Uncompensated High Slew Rate Operational Amplifiers

FEATURES

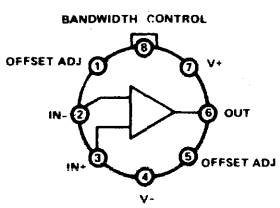
- HIGH SLEW RATE — 120V/μs
- FAST SETTLING — 200ns
- WIDE POWER BANDWIDTH — 2,000kHz
- HIGH GAIN BANDWIDTH — 20MHz
- HIGH INPUT IMPEDANCE — 100MΩ
- LOW OFFSET CURRENT — 10nA

APPLICATIONS

- DATA ACQUISITION SYSTEMS
- R.F. AMPLIFIERS
- VIDEO AMPLIFIERS
- SIGNAL GENERATORS
- PULSE AMPLIFICATION

DESCRIPTION

HA-2520/2522/2525 comprise a series of monolithic operational amplifiers delivering an unsurpassed combination of specifications for slew rate, bandwidth and settling time. These dielectrically isolated amplifiers are controlled at closed loop gains greater than 3 without external compensation. In additon, these high performance components also provide low offset current and high input impedance.



120V/μs slew rate and 200ns (0.1%) settling time of these amplifiers make them ideal components for pulse amplification and data acquisition designs. These devices are valuable components for R.F. and video circuitry requiring up to 20MHz gain bandwidth and 2MHz power bandwidth. For accurate signal conditioning designs the HA-2520/2522/2525's superior dynamic specifications are complimented by 10nA offset current, 100MΩ input impedance and offset trim capability.

The HA-2520/2522 are available in metal can (TO-99) and 14-pin flat packages. HA-2520 and HA-2522 are specified over -55°C to +125°C range. HA-2525 is specified from 0°C to +75°C, and is available in the TO-99 package.

HA-2530/2535

High Slew Rate, Wideband Inverting Amplifier

FEATURES

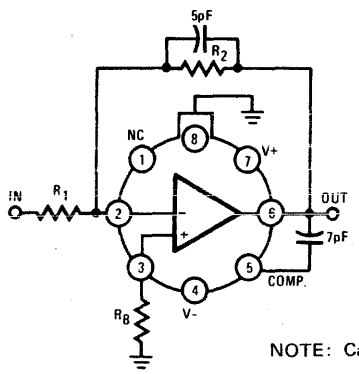
- HIGH SLEW RATE ±320V/μs
- FAST SETTLING TIME 550ns
- WIDE POWER BANDWIDTH 5MHz
- HIGH GAIN BANDWIDTH PRODUCT 70MHz
- LOW OFFSET VOLTAGE 0.8mV
- LOW POWER SUPPLY CURRENT 3.5mA

APPLICATIONS

- PULSE AMPLIFICATION
- SIGNAL CONDITIONING
- SIGNAL GENERATORS
- COAXIAL CABLE DRIVERS
- INTEGRATORS

DESCRIPTION

HA-2530 and HA-2535 are monolithic high speed inverting amplifiers which deliver superior slew rate, bandwidth, and accuracy specifications compared to any other amplifier in its class. Designs of these dielectrically isolated amplifiers utilize the feed forward amplifier technique to produce excellent dynamic and DC specifications coupled with low power consumption. These devices require no external compensation at closed loop gains greater than 10.



These amplifiers are excellent components for pulse circuits, data acquisition designs, and high speed integrators that can take advantage of the ±320V/μs slew rate and 550ns (0.1%) settling time. 70MHz gain bandwidth product, 5MHz power bandwidth coupled with 0.8mV offset voltage and ±50mA typical output current levels make these amplifiers ideally suited for signal conditioning, signal generation, and coaxial driver applications.

The HA-2530 and HA-2535 are available in metal can (TO-99) packages. HA-2530 is specified over the -55°C to +125°C range while HA-2535 is specified from 0°C to +75°C.

A DIVISION OF HARRIS CORPORATION

HA-2600/2602/2605

Wide Band, High Impedance Operational Amplifier

FEATURES

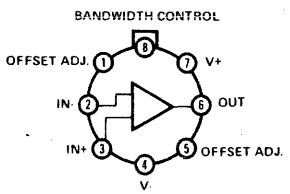
- WIDE BANDWIDTH — 12MHz
- HIGH INPUT IMPEDANCE — 500MΩ
- LOW INPUT BIAS CURRENT — 1nA
- LOW INPUT OFFSET CURRENT — 1nA
- LOW INPUT OFFSET VOLTAGE — 0.5mV
- HIGH GAIN — 150K V/V
- HIGH SLEW RATE — 7V/μs
- OUTPUT SHORT CIRCUIT PROTECTION

APPLICATIONS

- VIDEO AMPLIFIER
- PULSE AMPLIFIER
- AUDIO AMPLIFIERS AND FILTERS
- HIGH-Q ACTIVE FILTERS
- HIGH-SPEED COMPARATORS
- LOW DISTORTION OSCILLATORS

DESCRIPTION

HA-2600/2602/2605 are internally compensated bipolar operational amplifiers that feature very high input impedance (500 MΩ, HA-2600) coupled with wideband AC performance. The high resistance of the input stage is complemented by low offset voltage (0.5mV, HA-2600) and low bias and offset current (1nA, HA-2600) to facilitate accurate signal processing. Input offset can be reduced further by means of an external nulling potentiometer. 12MHz unity gain-bandwidth product, 7V/μs slew rate and 150,000V/V open-loop gain enables HA-2600/2602/2605 to perform high-gain amplification of fast, wideband signals. These dynamic characterisitics, coupled with fast settling times, make these amplifiers ideally suited to pulse amplification designs as well as high frequency (e.g. video) applications. The frequency response of the amplifier can be tailored to exact design requirements by means of an external bandwidth control capacitor.



In addition to its application in pulse and video amplifier designs, HA-2600/2602/2605 is particularly suited to other high performance designs such as high-gain low distortion audio amplifiers, high-Q and wideband active filters and high-speed comparators.

HA-2600 and HA-2602 are guaranteed over -55°C to +125°C. HA-2605 is specified from 0°C to +75°C. All devices are available in TO-99 cans, and HA-2600/2602 are available in 10 lead flat packages.

OUTPUT SWING = ± 10V MIN. TO 50kHz

*A small load capacitance is recommended in all applications where practical to prevent possible high frequency oscillations resulting from external wiring parasitics. Capacitance up to 100pF has negligible effect on the bandwidth or slew rate.

DEFINITIONS

INPUT OFFSET VOLTAGE – That voltage which must be applied between the input terminals through two equal resistances to force the output voltage to zero.

INPUT OFFSET CURRENT – The difference in the currents into the two input terminals when the output is at zero voltage.

INPUT BIAS CURRENT – The average of the currents flowing into the input terminals when the output is at zero voltage.

INPUT COMMON MODE VOLTAGE – The average referred to ground of the voltages at the two input terminals.

COMMON MODE RANGE – The range of voltages which is exceeded at either input terminal will cause the amplifier to cease operating.

COMMON MODE REJECTION RATIO – The ratio of a specified range of input common mode voltage to the peak-to-peak change in input offset voltage over this range.

OUTPUT VOLTAGE SWING – The peak symmetrical output voltage swing, referred to ground, that can be obtained without clipping.

INPUT RESISTANCE – The ratio of the change in input voltage to the change in input current.

OUTPUT RESISTANCE – The ratio of the change in output voltage to the change in output current.

VOLTAGE GAIN – The ratio of the change in output voltage to the change in input voltage producing it.

BANDWIDTH – The frequency at which the voltage gain is 3dB below its low frequency value.

UNITY GAIN BANDWIDTH – The frequency at which the voltage gain of the amplifier is unity.

POWER SUPPLY REJECTION RATIO – The ratio of the change in input offset voltage to the change in power supply voltage producing it.

TRANSIENT RESPONSE – The closed loop step function response of the amplifier under small signal conditions.

PHASE MARGIN – $(180^o - (\phi_1 - \phi_2))$ where ϕ_1 is the phase shift at the frequency where the absolute magnitude of gain is unity ϕ_2 is the phase shift at a frequency much lower than the open loop bandwidth.

SLEW RATE (Rate Limiting) – The rate at which the output will move between full scale stops, measured in terms of volts per unit time. This limit to an ideal step function response is due to the non-linear behavior in an amplifier due to its limited ability to produce large, rapid changes in output voltage (slewing) . . . restricting it to rates of change of voltage lower than might be predicted by observing the small signal frequency response.

SETTLING TIME – Time required for output waveform to remain within 0.1% of final value.

HA-2620/2622/2625

Very Wide Band, Uncompensated Operational Amplifiers

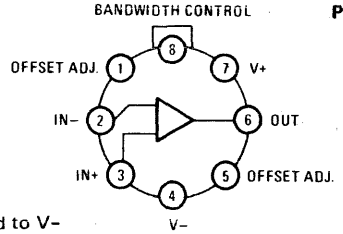
FEATURES

- GAIN BANDWIDTH PRODUCT(A_V = 5) 100MHz
- HIGH INPUT IMPEDANCE 500MΩ
- LOW INPUT BIAS CURRENT 1nA
- LOW INPUT OFFSET CURRENT 1nA
- LOW INPUT OFFSET VOLTAGE 0.5mV
- HIGH GAIN 150K V/V
- HIGH SLEW RATE 35V/μs
- OUTPUT SHORT CIRCUIT PROTECTION

APPLICATIONS

- VIDEO AND R.F. AMPLIFIERS
- PULSE AMPLIFIER
- AUDIO AMPLIFIERS AND FILTERS
- HIGH-Q ACTIVE FILTERS
- HIGH-SPEED COMPARATORS
- LOW DISTORTION OSCILLATORS

DESCRIPTION



HA-2620/2622/2625 are bipolar operational amplifiers that feature very high input impedance (500MΩ, HA-2620) coupled with wideband AC performance. The high resistance of the input stage is complemented by low offset voltage (0.5mV, HA-2620) and low bias and offset current (1nA, HA-2620) to facilitate accurate signal processing. Input offset can be reduced further by means of an external nulling potentiometer. 100MHz gain-bandwidth product (HA-2620/2622/2625 are stable for closed loop gains greater than 5), 35V/ μs slew rate and 150,000V/V open-loop gain enables HA-2620/2622/2625 to perform high-gain amplification of very fast, wideband signals. These dynamic characterisitcs, coupled with fast settling times, make these amplifiers ideally suited to pulse amplification designs as well as high frequiency (e.g. video) applications. The frequency response of the amplifier can be tailored to exact design requirements by means of an external bandwidth control capacitor.

In addition to its application in pulse and video amplifier designs HA-2620/2622/2625 is particularly suited to other high performance designs such as high-gain low distortion audio amplifiers, high-Q and wideband active filters and high-speed comparators.

HA-2620 and HA-2622 are guaranteed over -55°C to +125°C. HA-2625 is specified from 0°C to +75°C. All devices are available in TO-99 cans, and 14 lead D.I.P. packages.

DEFINITIONS

INPUT OFFSET VOLTAGE—That voltage which must be applied between the input terminals through two equal resistances to force the output voltage to zero.

INPUT OFFSET CURRENT—The difference in the currents into the two input terminals when the output is at zero voltage.

INPUT BIAS CURRENT—The average of the currents flowing into the input terminals when the output is at zero voltage.

INPUT COMMON MODE VOLTAGE—The average referred to ground of the voltages at the two input terminals.

COMMON MODE RANGE—The range of voltages which is exceeded at either input terminal will cause the amplifier to cease operating.

COMMON MODE REJECTION RATIO—The ratio of a specified range of input common mode voltage to the peak-to-peak change in input offset voltage over this range.

OUTPUT VOLTAGE SWING—The peak symmetrical output voltage swing, referred to ground, that can be obtained without clipping.

INPUT RESISTANCE—The ratio of the change in input voltage to the change in input current.

OUTPUT RESISTANCE—The ratio of the change in output voltage to the change in output current.

VOLTAGE GAIN—The ratio of the change in output voltage to the change in input voltage producing it.

UNITY GAIN BANDWIDTH—The frequency at which the voltage gain of the amplifier is unity.

POWER SUPPLY REJECTION RATIO—The ratio of the change in input offset voltage to the change in power supply voltage producing it.

TRANSIENT RESPONSE—The closed loop step function response of the amplifier under small signal conditions.

GAIN BANDWIDTH PRODUCT—The product of the gain and the bandwidth at a given gain.

SLEW RATE (Rate Limiting)—The rate at which the output will move between full scale stops, measured in terms of volts per unit time. This limit to an ideal step function response is due to the non-linear behavior in an amplifier due to its limited ability to produce large, rapid changes in output voltage (slewing)...restricting it to rates of change of voltage lower than might be predicted by observing the small signal frequency response.

HA-2630/2635

High Performance Current Booster

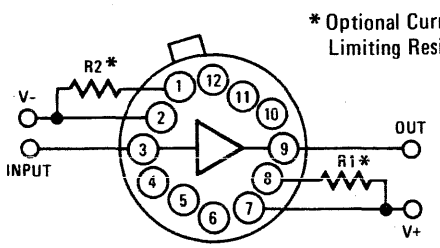
FEATURES

- OUTPUT CURRENT ±400mA
- SLEW RATE 500V/μs
- BANDWIDTH 8MHz
- FULL POWER BANDWIDTH 8MHz
- INPUT RESISTANCE $2.0 \times 10^6 \Omega$
- OUTPUT RESISTANCE 2.0Ω
- POWER SUPPLY RANGE ±5V to ±20V
- PACKAGE IS ELECTRICALLY ISOLATED

APPLICATIONS

- COAXIAL CABLE DRIVERS
- AUDIO OUTPUT AMPLIFIERS
- SERVO MOTOR DRIVERS
- POWER SUPPLIES (BIPOLAR)
- PRECISION DATA RECORDING

DESCRIPTION



HA-2630 and HA-2635 are monolithic, unity voltage gain current amplifiers delivering extremely high slew rate, wide bandwidth, and full power bandwidth even under heavy output loading conditions. This dielectrically isolated current booster also offers high input impedance and low output resistance. These devices are intended to be used in series with an operational amplifier and inside the feedback loop whenever additional output current is required. Output current levels are programmable by selecting two optional external resistors.

These current amplifiers offer an exceptional 500V/μs slew rate and 8MHz bandwidth which allows them to be used with many high performance op amps in precision data recording and high speed coaxial cable driver designs. 2.0M ohm input resistance and 2 ohm output resistance coupled with ±400mA output current make HA-2630 and HA-2635 ideal components in high fidelity audio output amplifier designs.

HA-2630 and HA-2635 are available in an electrically isolated TO-8 type can for ease of mounting with or without a heat sink. HA-2630 is specified over the -55°C to +125°C range. HA-2635 is specified from 0°C to +75°C.

HA-2640/2645

High Voltage Operational Amplifier

FEATURES

- OUTPUT VOLTAGE SWING ±35V
- SUPPLY VOLTAGE ±10V TO ±40V
- OFFSET CURRENT 5nA
- BANDWIDTH 4MHz
- SLEW RATE 5V/μs
- COMMON MODE INPUT VOLTAGE SWING ±35V
- OUTPUT OVERLOAD PROTECTION

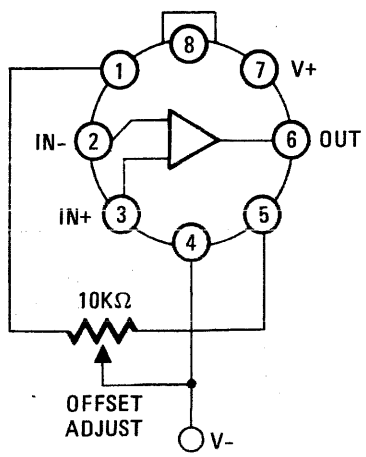
APPLICATIONS

- INDUSTRIAL CONTROL SYSTEMS
- POWER SUPPLIES
- HIGH VOLTAGE REGULATORS
- RESOLVER EXCITATION
- SIGNAL CONDITIONING

DESCRIPTION

HA-2640 and HA-2645 are monolithic operational amplifiers which are designed to deliver unprecedented dynamic specifications for a high voltage internally compensated device. These dielectrically isolated devices offer very low values for offset voltage and offset current coupled with large output voltage swing and common mode input voltage.

For maximum reliability, these amplifiers offer unconditional output overload protection through current limiting and a chip temperature sensing circuit. This sensing device turns the amplifier "off", when the chip reaches a certain temperature level.



These amplifers deliver ±35V common mode input voltage swing, ±35V output voltage swing, and up to ±40V supply range for use in such designs as regulators, power supplies, and industrial control systems. 4MHz gain bandwidth and 5V/μs slew rate make these devices excellent components for high performance signal conditioning applications. Outstanding input and output voltage swings coupled with a low 5nA offset current make these amplifiers excellent components for resolver excitation designs.

HA-2640 and HA-2645 are available in metal can (TO-99) packages and can be used as high performance pin-to-pin replacements for many general purpose op amps. HA-2640 is specified from -55°C to +125°C and HA-2645 is specified over the 0°C to +75°C range.

HA-2650/2655

Dual High Performance Operational Amplifier

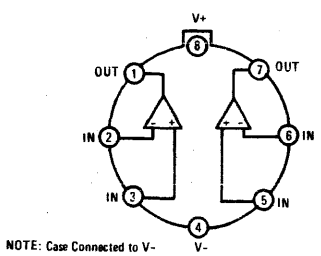
FEATURES

- SLEW RATE — 5V/μs
- BANDWIDTH — 8MHz
- BIAS CURRENT — 35nA
- AV. OFFSET VOLTAGE DRIFT — 8μV/°C
- POWER CONSUMPTION — 75mW
- SUPPLY VOLTAGE RANGE — ±2V TO ±20V

APPLICATIONS

- VIDEO AMPLIFIERS
- HIGH IMPEDANCE, WIDEBAND BUFFERS
- INTEGRATORS
- AUDIO AMPLIFIERS
- ACTIVE FILTERS

DESCRIPTION



HA-2650/2655 contains two internally compensated operational amplifiers offering high slew rate and high frequency performance combined with exceptional DC characteristics. 5V/μ sec slew rate and 8MHz bandwidth make these amplifiers suitable for processing fast, wideband signals extending into the video frequency spectrum. Signal processing accuracy is enhanced by front-end performance that includes 1.5mV offset voltage, 8 μ V/°C offset voltage drift and low offset and bias current (1nA and 35nA respectively). Offset voltage can be trimmed to zero on the devices offered in dual-in-line packages. Signal conditioning is further enhanced by 500MΩ input impedance.

Applications for HA-2650/2655 include video circuit designs such as high impedance buffers, integrators, tone generators and filters. These amplifiers are also ideal components for active filtering of audio and voice signals.

HA-2650/2655 are offered in 14 pin D.I.P. and metal TO-99 packages and are also available in dice form. HA-2650 is specified from -55°C to +125°C. HA-2655 operates from 0°C to +75°C.

HA-2700/2704/2705

Low Power, High Performance Operational Amplifiers

FEATURES

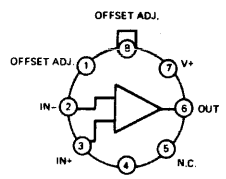
- LOW POWER DISSIPATION — 2.24mW AT ±15.0V
- HIGH SLEW RATE — 20V/μs
- HIGH OPEN LOOP GAIN — 300K(R_L = 2KΩ)
- LOW INPUT BIAS CURRENT — 5nA
- LOW OFFSET VOLTAGE — 0.5mV
- HIGH CM_{rr} — 106dB
- WIDE POWER SUPPLY RANGE — ±5.5V TO ±20.0V

APPLICATIONS

- HIGH GAIN AMPLIFIER
- INSTRUMENTATION AMPLIFIERS
- ACTIVE FILTERS
- TELEMETRY SYSTEMS
- BATTERY-POWERED EQUIPMENT

DESCRIPTION

HA-2700/2704/2705 are internally compensated operational amplifiers which employ dielectric isolation to achieve excellent DC and dynamic performance with very low quiescent power consumption.



DC performance of the amplifier input is characterized by high CMRR (106dB), low offset voltage (0.5mV, HA-2700 and HA-2704; 1mV, HA-2705) along with low bias and offset current (5.0nA and 2.5nA respectively). These input specifications, in conjunction with offset null capability and open-loop gain of 300,000V/V, enable HA-2700/2704/2705 to provide accurate, high-gain signal amplification. Gain bandwidth 1MHz and slew rate of 20V/μs allow for processing of fast, wideband signals. Input and output signal amplitudes of at least ±11 volts can be accomodated while providing output drive capability of 10mA. For maximum reliability, the output is protected in the event of short circuits to ground.

These amplifiers operate from a wide range of supplies (±5.5V to ±20V) with a maximum quiescent supply drain of only 150μA. HA-2700/2704/2705 are, therefore, ideally suited to low-power instrumentation and filtering applications that require fast, accurate response over a wide range of signal frequency.

These amplifers are available in three performance grades: HA-2700 is rated for operation from -55°C to +125°C; HA-2704 is specified over -25°C to +85°C; HA-2705 is specified from 0°C to +75°C. All three devices are available in TO-99 cans or 14 lead D.I.P. packages.

HA-2720/25

Wide Range Programmable Operational Amplifier

FEATURES

- WIDE PROGRAMMING RANGE

SLEW RATE	0.06 TO 6V/μs
BANDWIDTH	5kHz TO 10MHz
BIAS CURRENT	0.4 TO 50nA
SUPPLY CURRENT	1μA TO 1.5mA

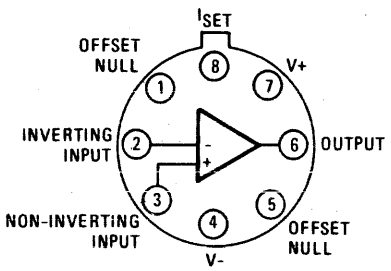
- WIDE POWER SUPPLY RANGE ±1.2 TO ±18V
- CONSTANT AC PERFORMANCE OVER SUPPLY RANGE

APPLICATIONS

- ACTIVE FILTERS
- CURRENT CONTROLLED OSCILLATORS
- VARIABLE ACTIVE FILTERS
- MODULATORS
- BATTERY-POWERED EQUIPMENT

DESCRIPTION

HA-2720/2725 programmable amplifiers are internally compensated monolithic devices offering a wide range of performance, that can be controlled by adjusting the circuits' "set" current (I_{SET}). By means of adjusting an external resistor or current source, power dissipation, slew rate, bandwidth, output current and input noise can be programmed to desired levels. This versatile adjustment capability enables HA-2720/2725 to provide optimum design solutions by delivering the required level of performance with minimum possible power dissipation. HA-2720 and HA-2725 can, therefore, be utilized as the standard amplifier for a variety of designs simply by adjusting their programming current.



A major advantage of HA-2720/2725 is that operating characteristics remain virtually constant over a wide supply range (±1.2V to ±15V), allowing the amplifiers to offer maximum performance in almost any system including battery-operated equipment. A primary application for HA-2720/2725 is in active filters for a wide variety of signals that differ in frequency and amplitude. Also, by modulating the "set" current, HA-2720/2725 can be used for designs such as current controlled oscillators modulators, sample and hold circuits and variable active filters.

HA-2720 is guaranteed over -55°C to +125°C. HA-2725 is specified from 0°C to +75°C. Both parts are available in TO-99 cans or dice form.

HA-2900/04/05

Chopper Stabilized Operational Amplifier

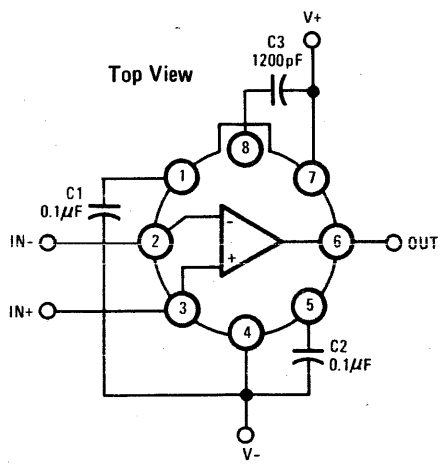
FEATURES

- OFFSET VOLTAGE DRIFT — 0.2 μV/°C
- OFFSET CURRENT DRIFT — 1pA/°C
- OPEN LOOP GAIN — 5×10^8
- BANDWIDTH — 3MHz
- SLEW RATE — 2.5V/μs
- TRUE DIFFERENTIAL INPUTS

APPLICATIONS

- HIGH-GAIN DC INSTRUMENTATION
- HIGH-ACCURACY WEIGHING EQUIPMENT
- BIOMEDICAL AMPLIFIERS
- PRECISION INTEGRATORS AND TIMERS

DESCRIPTION



HA-2900/2904/2905 are monolithic chopper-stabilized operational amplifiers that employ dielectric isolation achieving superior offset drift, extremely low input currents and excellent AC performance. Input drift is characterized by offset voltage drift of 0.2 μV/°C and offset current drift of 1pA/°C. Initial offset voltage is only 20 μV while offset current is 50pA. These input specifications make HA-2900/2904/2905 ideally suited to high accuracy applications such as high-gain DC instrumentation, and precision integration. The amplifiers can be used to replace other op amps in designs where much lower errors are required without external adjustments. 3MHz gain-bandwidth product makes HA-2900/2904/2905 valuable for processing wide band signals as well as for low frequency measurements.

In addition to offering high-accuracy performance, these "choppers" also offer versatility by virtue of their symmetrical, differential inputs which permit operation in any op amp configuration – inverting, non-inverting or balanced. These devices require only three external capacitors for proper operation.

HA-2900 is guaranteed over -55°C to +125°C; HA-2904 operates from -25°C to +85°C; HA-2905 operates from 0°C to +75°C. All devices are available in a hermetically sealed metal can.

NOTE: Measured on both positive and negative transitions.

APPLICATION TIPS

(1) Device inputs should be protected against exceeding either supply voltage from static discharge or inadvertent connection, particularly when wired directly to a connector or instrument panel.

(2) External capacitors C1, C2, and C3 should have good temperature stability, low leakage, and low dielectric absorption. Polystyrene (below +85°C), teflon types or polycarbonate are recommended. C3 could also be silver mica.

(3) Particular care must be exercised in system layout and material and component selection to realize the full performance potential of the HA-2900/2904/2905. External sources of drift error may include the thermocouple and electrochemical EMF's generated at junctions of dissimilar metals, leakage across insulating materials, static charges created by moving air, and improper grounding and shielding practices.

(4) Chopper noise is present chiefly as a common mode input current signal, and may be minimized by matching the impedances at the two inputs. Random noise may be reduced at the expense of bandwidth using active or passive filtering.

(5) Input frequencies near the chopper frequency (750Hz) or its harmonics may result in small components of difference frequency in the output. This effect should be checked in the individual application, and if objectionable, a low pass filter may be added in series with the input.

(6) When operating at closed loop gains between 70 dB and 140 dB, compensation networks may be required, because of open loop phase shift in this gain region. In most cases, a capacitor placed in parallel with the feedback resistor to yield a gain-bandwidth product < 2MHz will be sufficient.

HARRIS SEMICONDUCTOR
A DIVISION OF HARRIS CORPORATION

HA-4602/4605

High Performance Quad Operational Amplifier

FEATURES

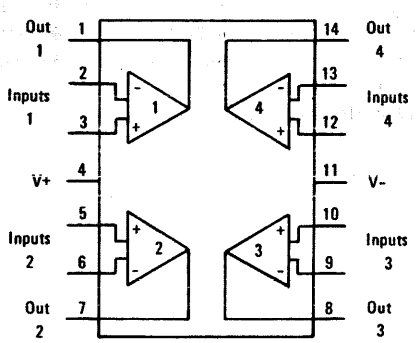
- LOW OFFSET VOLTAGE 0.3mV
- HIGH SLEW RATE ±4V/μs
- WIDE BANDWIDTH 8MHz
- LOW DRIFT 2μV/°C
- FAST SETTLING (0.01%, 10V STEP) 4.2μs
- LOW POWER CONSUMPTION 35mW/AMP
- SUPPLY RANGE ±5V TO ±20V

APPLICATIONS

- HIGH Q, WIDE BAND FILTERS
- INSTRUMENTATION AMPLIFIERS
- AUDIO AMPLIFIERS
- DATA ACQUISITION SYSTEMS
- INTEGRATORS
- ABSOLUTE VALUE CIRCUITS
- TONE DETECTORS

DESCRIPTION

The HA-4602 and HA-4605 are high performance dielectrically isolated monolithic quad operational amplifiers with superior specifications not previously available in a quad amplifier. These amplifiers offer excellent dynamic performance coupled with low values for offset voltage and drift, input noise voltage and power consumption.



A wide range of applications can be achieved by using the features made available by the HA-4602/4605. With wide bandwidth (8MHz), low power (35mW/amp), and internal compensation, these devices are ideally suited for precision active filter designs. For audio applications these amplifiers offer low noise ($8nV/\sqrt{Hz}$) and excellent full power bandwidth (60kHz). The HA-4602/4605 is particularly useful in designs requiring low offset voltage (0.3mV) and drift (2 μV/°C), such as instrumentation and signal conditioning circuits. The high slew rate (4V/μs) and fast settling time (4.2 μs to 0.01%, 10V step) makes these amplifiers useful components in fast, accurate data acquisition systems.

The HA-4602 and 4605's are available in 14 pin CERDIP packages which are interchangeable with most other quad op amps. HA-4602 is specified from -55°C to +125°C, and HA-4605 is specified over 0°C to +75°C range.

NOTES

1. Absolute maximum ratings are limiting values, applied individually, beyond which the serviceability of the circuit may be impaired. Functional operability under any of these conditions is not necessarily implied.
2. For supply voltages less than ±15V, the absolute maximum input voltage is equal to the supply voltage.
3. Any one amplifier may be shorted to ground indefinitely.
4. Derate 5.8mW/°C above T_A = +25°C.
5. V_{OUT} = ±10V; R_L = 2K ohms.
6. Channel separation value is referred to the input of the amplifier. Input test conditions are: f = 10kHz; V_{IN} = 200mV peak-to-peak; R_S = 1K ohms. (Refer to Channel Separation vs. Frequency Curve for test circuits.)
7. Output current is measured with V_{OUT} = ±5 volts. The output current specified can also be applied to V_{OUT} = ±10V.
8. For transient response test circuits and measurement conditions refer to Test Circuits section of the data sheet.
9. ΔV = ±5.0 volts.
10. Settling time is measured to 0.01% of final value for a 10 volt input step, A_V = -1.

1. POWER SUPPLY DECOUPLING: Although not absolutely necessary, it is recommended that all power supply lines be decoupled with .01 μ F ceramic capacitors to ground. Decoupling capacitors should be located as near to the amplifier terminals as possible.

2. UNUSED OP AMPS: Unused op amp sections should be connected in a non-inverting follower configuration with the (+) input tied to ground in order to insure optimum performance of devices being used.

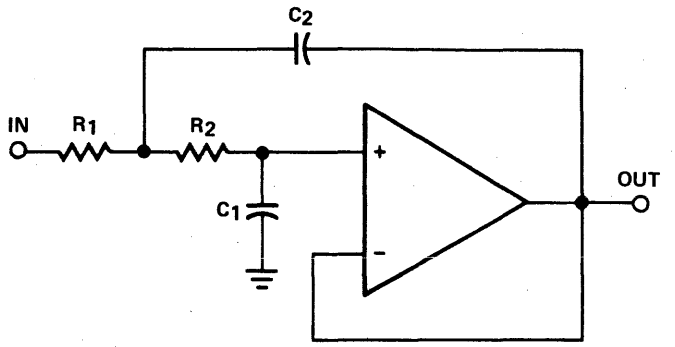
3. In high frequency applications where large value feedback resistors are used, a small capacitor (3pF) may be needed in parallel with the feedback resistor to neutralize the pole introduced by input capacitance.

APPLICATIONS

2ND ORDER STATE VARIABLE FILTER (1kHz, Q = 10)

NOTES: 1. MAKE $R_1C_1 = R_2C_2$

2. $f_c = \frac{1}{2\pi R_1 C_1}$



3. $Q = \frac{1}{2}\left(1 + \frac{R_6}{R_5}\right)$

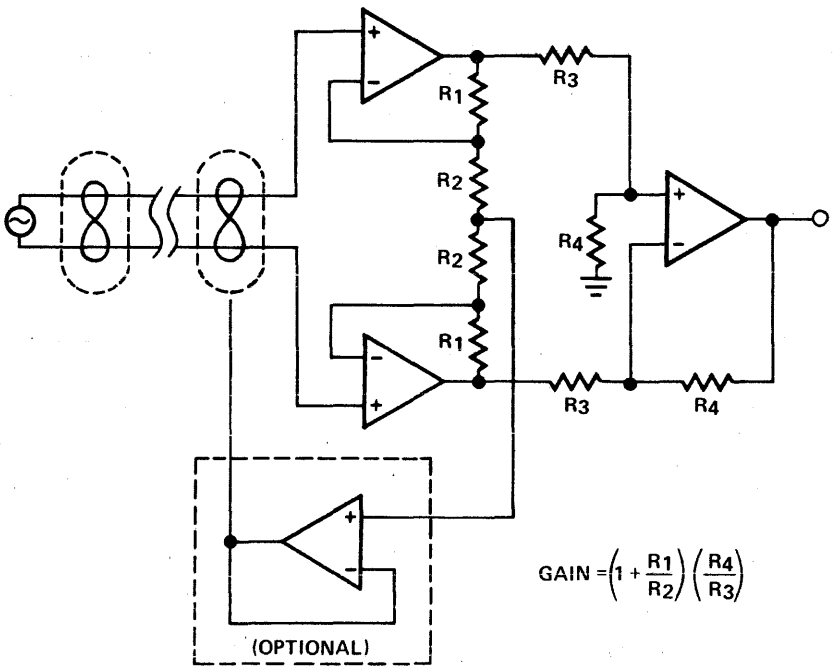
The state variable filter is relatively insensitive to component changes (changes can be adjusted out with potentiometers) and also has low sensitivity to amplifier bandwidths. (Amplifier gain bandwidth product should be $\gg Q \times f_C$). The bandwidth criteria will determine whether a general purpose op amp like Harris HA-4741 or the wide band HA-4602/4605 should be used.

This filter finds wide application because multiple filtering functions are available simultaneously (High pass, Lo pass, Band pass, Band reject). In this circuit the various RC products are matched with pot adjustments allowing for non-interactive adjustment of Q and f_C. This allows capacitors (C_1, C_2) with loose tolerances to be used. To tune for f_C, apply a sine wave at f_C to the input, adjust R_1 for equal amplitudes at the Hi pass and Band pass terminals (they will be phased 90° apart) then adjust R_2 for equal amplitudes at the Band pass and Lo pass terminals.

The state variable filter is often used as building blocks in multiple pole Butterworth of Chebyshev filters. Many references contain normalized tables indicating settings for Q and f_C of each pole-pair section.

SALLEN AND KEY 2ND ORDER LO PASS FILTER

NOTES:



1. Make $R_1 = R_2$
2. $f_c = \frac{1}{2\pi R_1\sqrt{C_1C_2}}$
3. $Q = \frac{1}{2}\sqrt{\frac{C_2}{C_1}}$

The advantage of using the Sallen and Key filter is simplicity, but in any application this must be weighed against the state-variable type filter for accuracy, practicality, and cost. Amplifier bandwidth limitations are much more apparent at moderate frequencies and Q values with this filter design. (For accuracy, amplifier gain-bandwidth product should be $\gg f_C \times Q^2$). The wide bandwidth of the HA-4602/4605 is particularly advantageous in this design even at audio frequencies.

In this filter all component values affect both Q and f_C. Precision, temperature stable resistors and capacitors must be used.

For economy, this filter could be used in the low Q stages of multiple-pole filter design, while the state variable type is used in the more critical stages.

INSTRUMENTATION AMPLIFIER

Instrumentation amplifiers (differential amplifiers) are specifically designed to extract and amplify small differential signals from much larger common mode voltages.

To serve as building blocks in instrumentation amplifiers, op amps must have very low offset voltage drift, high gain and wide bandwidth. The HA-4602/4605 is ideally suited for this application, delivering superior input and speed characteristics.

The optional circuitry makes use of the fourth amplifier section as a shield driver which enhances the AC common mode rejection by nullifying the effects of capacitance-to-ground mismatch between input conductors.

Quad Operational Amplifier

FEATURES

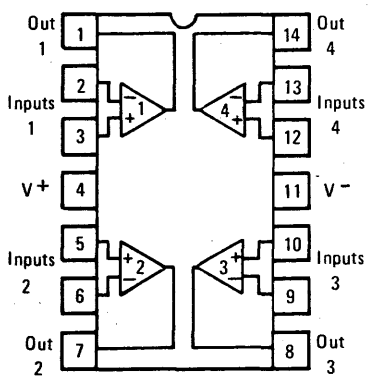
- SLEW RATE 1.6V/μs (TYP.)
- BANDWIDTH 3.5MHz (TYP.)
- INPUT VOLTAGE NOISE 9nV/$\sqrt{Hz}$ (TYP.)
- INPUT OFFSET VOLTAGE 0.5mV (TYP.)
- INPUT BIAS CURRENT 60nA (TYP.)
- SUPPLY RANGE ±2V TO ±20V
- NO CROSSOVER DISTORTION
- STANDARD QUAD PIN-OUT

APPLICATIONS

- UNIVERSAL ACTIVE FILTERS
- D3 COMMUNICATIONS FILTERS
- AUDIO AMPLIFIERS
- BATTERY-POWERED EQUIPMENT

DESCRIPTION

The HA-4741, which contains four amplifiers on a monolithic chip, provides a new measure of performance for general purpose operational amplifiers. Each amplifier in the HA-4741 has operating specifications that equal or exceed those of the 741-type amplifier in all categories of performance.



HA-4741 is well suited to applications requiring accurate signal processing by virtue of its low values of input offset voltage (0.5mV), input bias current (60nA) and input voltage noise (9nV/ $\sqrt{Hz}$ at 1kHz). 3.5MHz bandwidth, coupled with high open-loop gain, allow the HA-4741 to be used in designs requiring amplification of wide band signals, such as audio amplifiers. Audio application is further enhanced by the HA-4741's negligible output crossover distortion. These excellent dynamic characteristics also make the HA-4741 ideal for a wide range of active filter designs. Performance integrity of multi-channel designs is assured by a high level of amplifier-to-amplifier isolation (108dB at 1kHz).

A wide range of supply voltages (±2V to ±20V) can be used to power the HA-4741, making it compatible with almost any system including battery-powered equipment.

The HA-4741 has guaranteed operation over -55°C to +125°C and can be furnished to meet MIL-STD-883 (HA-4741-8). The HA-4741-5 is guaranteed over 0°C to +75°C and is available in ceramic and plastic dual-in-line packages and in dice form.

HA-4900/4905

Precision Quad Comparator

FEATURES

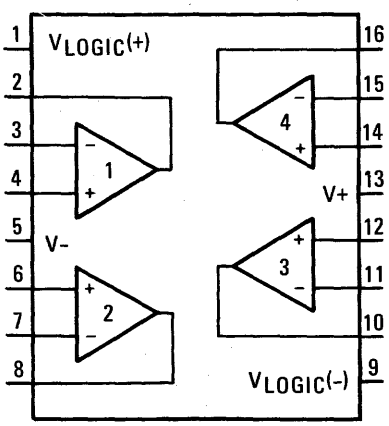
- FAST RESPONSE TIME 130ns
- LOW OFFSET VOLTAGE 2.0mV
- LOW OFFSET CURRENT 10nA
- SINGLE OR DUAL-VOLTAGE SUPPLY OPERATION
- SELECTABLE OUTPUT LOGIC LEVELS
- ACTIVE PULL-UP/PULL-DOWN OUTPUT CIRCUIT - NO EXTERNAL RESISTORS REQUIRED

APPLICATIONS

- THRESHOLD DETECTOR
- ZERO-CROSSING DETECTOR
- WINDOW DETECTOR
- ANALOG INTERFACES FOR MICROPROCESSORS
- HIGH STABILITY OSCILLATORS
- LOGIC SYSTEM INTERFACES

DESCRIPTION

The HA-4900/4905 are monolithic, quad, precision comparators offering fast response time, low offset voltage, low offset current, and virtually no channel-to-channel crosstalk for applications requiring accurate, high speed, signal level detection. These comparators can sense signals at ground level while being operated from either a single +5 volt supply (digital systems) or from dual supplies (analog networks) up to ±15 volts. The HA-4900/4905 contains a unique current driven output stage which can be connected to logic system supplies (V_{Logic}+ and V_{Logic}-) to make the output levels directly compatible (no external components needed) with any standard logic or special system logic levels. In combination analog/digital systems, the design employed in the HA-4900/4905 input and output stages prevents troublesome ground coupling of signals between analog and digital portions of the system.



These comparators' combination of features makes them ideal components for signal detection and processing in data acquisition systems, test equipment, and microprocessor/analog signal interface networks.

Both devices are available in 16 pin dual-in-line ceramic packages. The HA-4900 operates from -55°C to +125°C and the HA-4905 operates over a 0°C to +75°C temperature range.

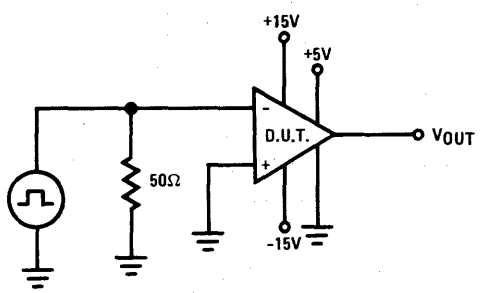
NOTES

1. Absolute maximum ratings are limiting values, applied individually, beyond which the serviceability of the circuit may be impaired. Functional operability under any of these conditions is not necessarily implied.

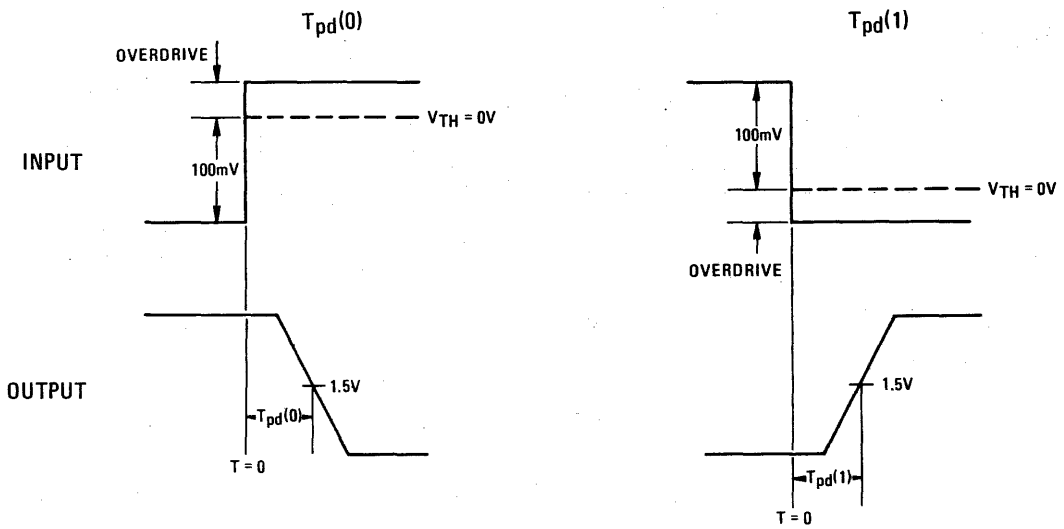
2. Minimum differential input voltage required to ensure a defined output state.

3. Input bias currents are essentially constant with differential input voltages up to ±9 volts. With differential input voltages from ±9 to ±15 volts, bias current on the more negative input can rise to approximately 500 μA.

4. $R_S \leq 200$ ohms; $V_{in} \leq$ Common Mode Range. Input sensitivity is the worst case minimum differential input voltage required to guarantee a given output logic state. This parameter includes the effects of offset voltage, offset current, common mode rejection, and voltage gain.



5. For $T_{pd}(1)$; 100mV input step,-5mV overdrive. For $T_{pd}(0)$; -100mV input step, 5mV overdrive. Frequency $\approx$ 100Hz; Duty Cycle $\approx$ 50%; Inverting input driven. See Test Circuit below.



6. For V_{OH} and V_{OL}: I_{Sink} = 3.5mA, I_{Source} = 3.0mA. For other values of V_{Logic}; V_{OH} (min.) = V_{Logic} + -1.5V.

7. Total Power Dissipation (T.P.D.) is the sum of individual dissipation contributions of V+, V- and V_{Logic} shown in curves of Power Dissipation vs. Supply Voltages (see page 5). The calculated T.P.D. is then located on the graph of Maximum Allowable Package Dissipation vs. Ambient Temperature (see page 5) to determine ambient temperature operating limits imposed by the calculated T.P.D.. For instance, the combination of +15V, -15V, +5V, 0V (V+, V-, V_{Logic}^+, V_{Logic}^-) gives a T.P.D. of 350mW which allows operation to +125°C; the combination +15V, -15V, +15V, 0V gives a T.P.D. of 450mW and an operating limit of T_A = +95°C.

8. Derate by 5.8mW/°C above T_A = +75°C.

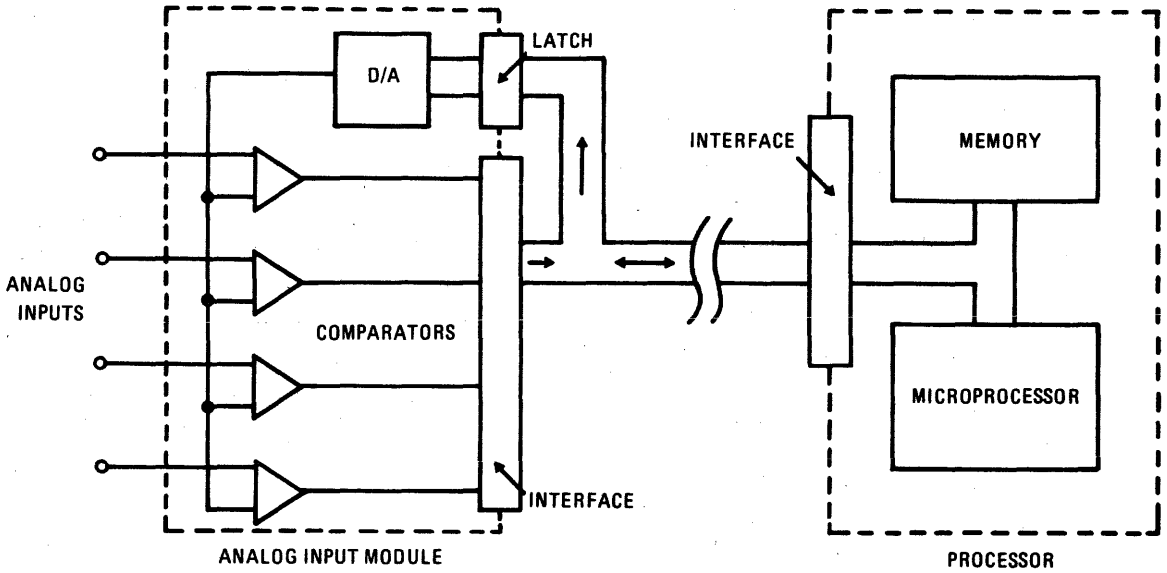
MAXIMUM PACKAGE DISSIPATION vs. $T_{AMBIENT}$

MAXIMUM POWER DISSIPATION vs. SUPPLY VOLTAGE (NO LOAD CONDITION)

APPLYING THE HA-4900/4905 COMPARATORS

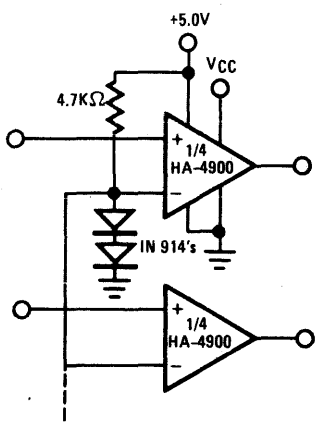


1. SUPPLY CONNECTIONS: This device is exceptionally versatile in working with most available power supplies. The voltage applied to the V+ and V- terminals determines the allowable input signal range; while the voltage applied to the V_L+ and V_L- determines the output swing. In systems where dual analog supplies are available, these would be connected to V+ and V-, while the logic supply and return would be connected to V_{Logic}+ and V_{Logic}-. The analog and logic supply commons can be connected together at one point in the system, since the comparator is immune to noise on the logic supply ground. A negative output swing may be obtained by connecting V_L+ to ground and V_L- to a negative supply. Bipolar output swings (15V P-P, max.) may be obtained using dual supplies. In systems where only a single logic supply is available (+5V to +15V), V+ and V_{Logic}+ may be connected together to the positive supply while V- and V_{Logic}- are grounded. If an input signal could swing negative with respect the V- terminal, a resistor should be connected in series with the input to limit input current to $< 5mA$ since the C-B junction of the input transistor would be forward biased.

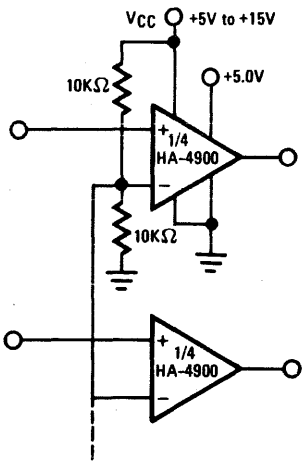
2. UNUSED INPUTS: Inputs of unused comparator sections should be tied to a differential voltage source to prevent output "chatter".

3. CROSSTALK: Simultaneous high frequency operation of all other channels in the package will not affect the output logic state of a given channel, provided that its differential input voltage is sufficient to define a given logic state ($\Delta V_{IN} \geq \pm V_{OS}$). Low level or high impedance input lines should be shielded from other signal sources to reduce crosstalk and interference.

4. POWER SUPPLY DECOUPLING: Decouple all power supply lines with .01 μ F ceramic capacitors to a ground line located near the package to reduce coupling between channnels or from external sources.



5. RESPONSE TIME: Fast rise time ($< 200ns$) input pulses of several volts amplitude may result in delay times somewhat longer than those illustrated for 100mV steps. Operating speed is optimized by limiting the maximum differential input voltage applied, with resistor-diode clamping networks.

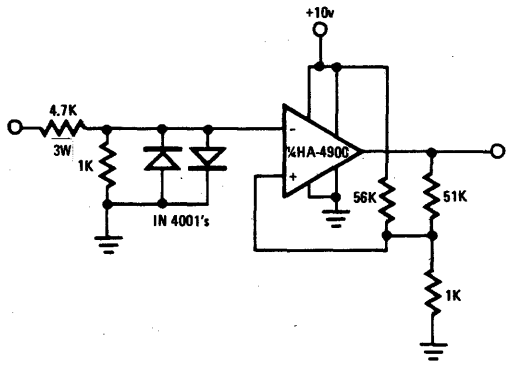


DATA ACQUISITION SYSTEM

In this circuit the HA-4900/4905 is used in conjunction with a D to A converter to form a simple, versatile, multi-channel analog input for a data acquisition system. In operation the processor first sends an address to the D to A, then the processor reads the digital word generated by the comparator outputs.

To perform a simple comparison, the processor sets the D to A to a given reference level, then examines one or more comparator outputs to determine if their inputs are above or below the reference. A window comparison consists of two such cycles with 2 reference levels set by the D to A. One way to digitize the inputs would be for the processor to increment the D to A in steps. The D to A address, as each comparator switches, is the digitized level of the input. While stairstepping the D to A is slower than successive approximation, all channels are digitized during one staircase ramp.

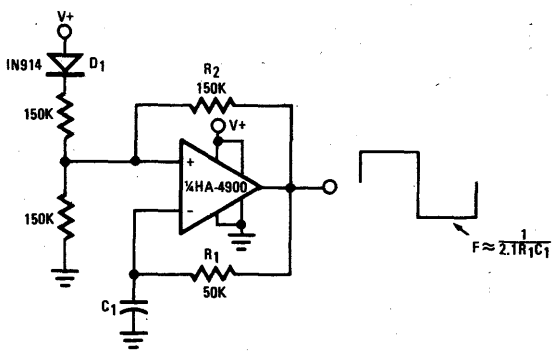
TTL TO CMOS



CMOS TO TTL

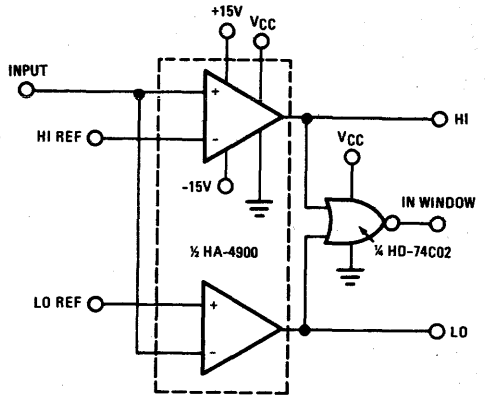
LOGIC LEVEL TRANSLATORS

The HA-4900/4905 comparators can be used as versatile logic interface devices as shown in the circuits above. Negative logic devices may also be interfaced with appropriate supply connections.



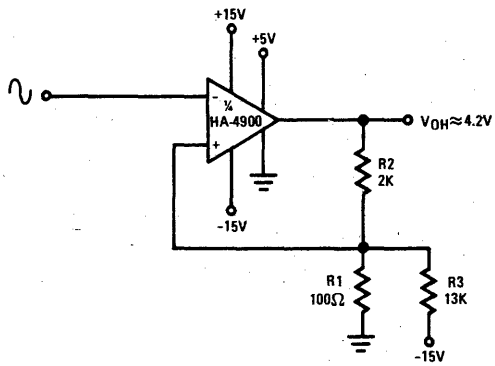
If separate supplies are used for V- and V_{Logic}-, these logic level translators will tolerate several volts of ground line differential noise.

©IC MASTER 1978



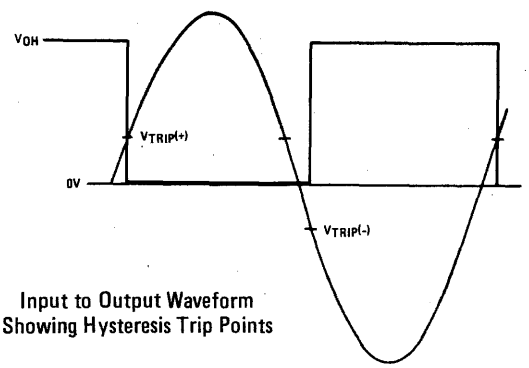
RS-232 TO CMOS LINE RECEIVER

This RS-232 type line receiver to drive CMOS logic uses a Schmitt trigger feedback network to give about 1 volt input hysteresis for added noise immunity. A possible problem in an interface which connects two equipments, each plugged into a different AC receptacle, is that the power line voltage may appear at the receiver input when the interface connection is made or broken. The two diodes and a 3 watt input resistor will protect the inputs under these conditions.



OSCILLATOR/CLOCK GENERATOR

This self-starting fixed frequency oscillator circuit gives excellent frequency stability. R_1 and C_1 comprise the frequency determining network while R_2 provides the regenerative feedback. Diode D_1 enhances the stability by compensating for the difference between V_{OH} and V_{Supply}. In applications where a precision clock generator up to 100kHz is required, such as in automatic test equipment, C_1 may be replaced by a crystal.



WINDOW DETECTOR

The high switching speed, low offset current and low offset voltage of the HA-4900/4905 makes this window detector circuit extremely well suited to applications requiring fast, accurate, decision-making. The circuit above is ideal for industrial process system feedback controllers or "out-of-limit" alarm indicators.

SCHMITT TRIGGER (ZERO CROSSING DETECTOR WITH HYSTERESIS)

This circuit has a 100mV hysteresis which can be used in applications where very fast transition times are required at the output even though the signal input is very slow. The hysteresis loop also reduces false triggering due to noise on the input. The waveforms below show the trip points developed by the hysteresis loop.

Input to Output Waveform
Showing Hysteresis Trip Points

HA-2420/2425

Fast Sample and Hold Gated Operational Amplifier

FEATURES

- SAMPLE CURRENT/HOLD RATIO 10^6
- ACQUISITION TIME (0.01%) 5μs
- SLEW RATE 5V/μs
- BANDWIDTH 2MHz
- APERTURE DELAY 50ns
- LOW CHARGE TRANSFER 10pC
- DTL/TTL COMPATIBLE CONTROL INPUT

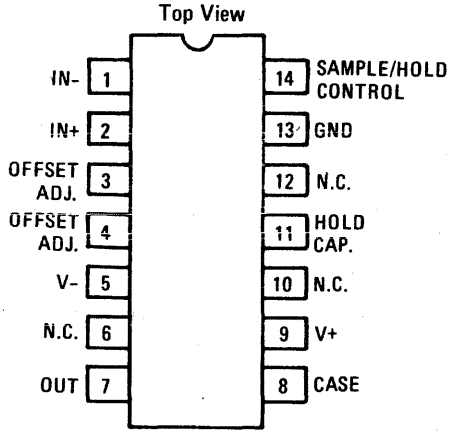
APPLICATIONS

- A TO D INPUT (TO 13 BITS)
- D TO A DEGLITCHER
- AUTO ZERO SYSTEMS
- PEAK DETECTOR
- GATED OP AMP

DESCRIPTION

The HA-2420/2425 is a monolithic circuit consisting of a high performance operational amplifier with its output in series with an ultra-low leakage analog switch and a MOSFET input unity gain amplifier.

With an external holding capacitor connected to the switch output, a versatile, high performance sample-and-hold or track-and-hold circuit is formed. When the switch is closed, the device behaves as an operational amplifier, and any of the standard op amp feedback networks may be connected around the device to control gain, frequency response, etc. When the switch is opened the output will remain at its last level.



Performance as a sample-and-hold compares very favorably with other monolithic, hybrid, modular, and discrete circuits. Accuracy to better than 0.01% is achievable over the temperature range. Fast acquisition is coupled with superior droop characteristics, even at high temperatures. High slew rate, wide bandwidth, and low acquisition time produce excellent dynamic characteristics. The ability to operate at gains greater than 1 frequently eliminates the need for external scaling amplifiers.

The device may also be used as a versatile operational amplifier with a gated output for applications such as analog switches, peak holding circuits, etc.

NOTES:
1) Figure 1 shows a typical unity gain circuit, with offset zeroing. All of the other normal op amp feedback configurations may be used with the HA-2420/2425. The input amplifier may be used as a gated amplifier by utilizing Pin 11 as the output. This amplifier has excellent drive capabilities along with exceptionally low switch leakage.
2) The method used to reduce leakage paths on the P.C. board and the device package is shown in Figure 2. This guard ring is recommended to minimize the drift during hold characteristic.
3) The holding capacitor should have extremely high insulation resistance and low dielectric absorption. Polystyrene (below +85°C), Teflon, or Parlene types are recommended.

For more applications, consult Harris Application Note 517.

GLOSSARY OF TERMS

ACQUISITION TIME:
The time required by the device after the "sample" command to reach its final value within ±0.1% or ±0.01%. This time includes switch delay time, slewing time and settling time. This is the minimum sample time required to obtain a given accuracy.

CHARGE TRANSFER:
The small charge transferred to the holding capacitor from the inter-electrode capacitance of the switch when the unit is switched to the Hold mode. Sample-to-Hold offset error is directly proportional to this charge, where:

$$\text{Offset Error (V)} = \frac{\text{Charge (pC)}}{C_H(\text{pF})}$$

APERTURE DELAY:
The time required after the "hold" command until the switch is fully open. This delays the effective sample timing with rapidly changing input signals.

DRIFT CURRENT:
Leakage currents from the holding capacitor during the Hold mode which cause the output voltage to drift. Drift rate (droop rate) can be calculated from drift current values using the formula:

$$\frac{\Delta V}{\Delta T}\,(\text{Volts/Sec}) = \frac{I(\text{pA})}{C_H(\text{pF})}$$

HA-2820/2825

Phase Locked Loop

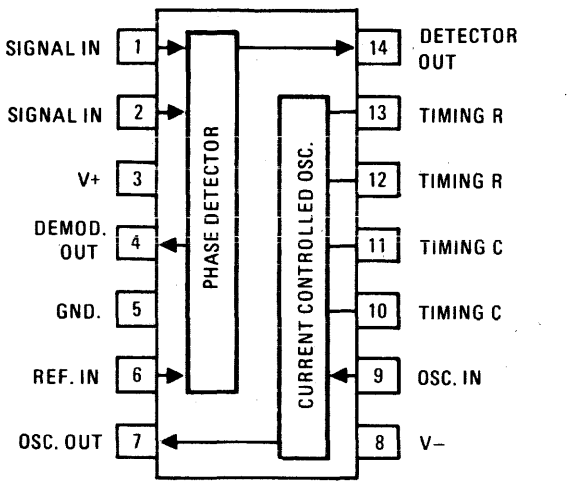
FEATURES

- FREQUENCY RANGE 0.01Hz tTO 3MHz
- INDEPENDENT PHASE DETECTOR AND OSCILLATOR FOR VERSATILITY
- TWO ISOLATED PHASE DETECTOR OUTPUTS
- DTL/TTL COMPATIBLE OSCILLATOR OUTPUT

APPLICATIONS

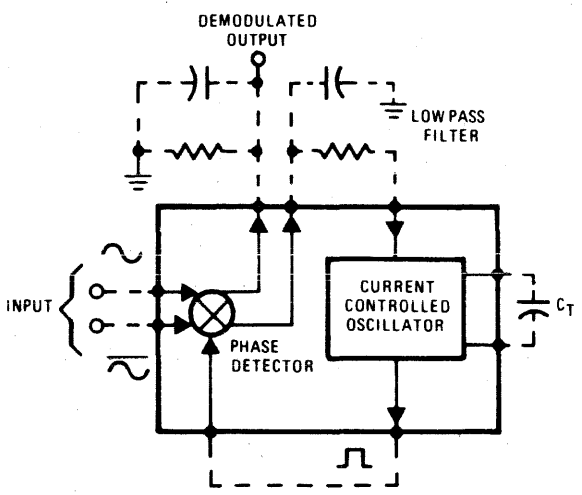
- DISCRIMINATORS
- RECEIVERS
- DATA DECODERS (DATA MODEMS)
- DATA SYNCHRONIZERS

DESCRIPTION



The HA-2820/2825 Phase Locked Loop is useful for many operations in the frequency domain in the sub-audio to low R. F. bands. It features a number of functional and parametric improvements over other similar monolithic circuits.

A major feature is a high impedance current source phase detector output with provisions for external connection to the oscillator input which is a low impedance current sink. This allows connection of complex passive or active filters, amplifiers, sweep circuits, etc. within the loop. Also, the two phase detector outputs are isolated from one another so that different filter functions can be connected at the two outputs without interaction. The capability of independently adjusting loop bandwidth allows phase modulation detectors to be constructed.



Applications include modulators and demodulators for F.M., phase modulation, and F.S.K.. frequency multiplication; data synchronization. tracking filters. and speed controls.

HC-55516/55532

All-Digital Continuously Variable Slope Delta Modulator (CVSD)

FEATURES

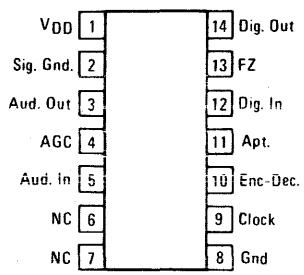
- REQUIRES FEWER EXTERNAL PARTS
- LOW POWER DRAIN: 6mW FROM SINGLE 5V-7V SUPPLY
- TIME CONSTANTS DETERMINED BY CLOCK FREQUENCY; NO CALIBRATION OR DRIFT PROBLEMS; AUTOMATIC OFFSET ADJUSTMENT
- HALF DUPLEX OPERATION BY DIGITAL CONTROL
- FILTER RESET BY DIGITAL CONTROL
- AUTOMATIC OVERLOAD RECOVERY
- AUTOMATIC "QUIET" PATTERN GENERATION
- AGC CONTROL SIGNAL AVAILABLE

APPLICATIONS

- VOICE TRANSMISSION OVER DATA CHANNELS
- VOICE ENCRYPTION/SCRAMBLING
- VOICE I/O FOR DIGITAL SYSTEMS
- AUDIO MANIPULATIONS: DELAY LINES, TIME COMPRESSION, ECHO GENERATION/ SURPRESSION, SPECIAL EFFECTS, ETC.

DESCRIPTION

The HC-55516 and HC-55532 are half duplex modulator/ demodulator CMOS integrated circuits used to convert voice signals into serial NRZ digital data, and to reconvert that data into voice. The conversion is by delta modulation, using the continuously variable slope (CVSD) method of companding.



While signals are compatible with other CVSD circuits, internal design is unique. The analog loop filters have been replaced by digital filters, using very low power, and requiring no external timing components. This approach allows inclusion of many desirable features which would be difficult to implement using other approaches.

The HC-55516 has internal time constants optimized for 16K bits/sec data rate and is usable down to 9K bits/sec. The HC-55532 is optimized for 32K bits/sec and is usable beyond 64K bits/sec. Both units are available in 14 pin D.I.P. (HC1) or flat packages (HC9) in two temperature ranges; -55°C to +125°C (-2 or -8) and -40°C to +85°C (-9).

©IC MASTER 1978

PIN # 14-LEAD F.P. & D.I.P.	SYMBOL	ACTIVE* LEVEL	DESCRIPTION
1	V_{DD}		Positive supply voltage.
2	Sig. Gnd.		Ground connection to D/A ladders and comparator; i.e. audio ground.
3	Aud. Out		Recovered audio out. May be used as side tone at the transmitter. Presents approximately 100 kilohm source. Zero signal reference is $V_{DD}/2$.
4	AGC		A logic "Low" level will appear at this output when the recovered signal excursion reaches one-half of full scale value.
5	Aud. In		Audio input. Should be externally AC coupled. Presents approximately 100 kilohms in series with $V_{DD}/2$.
6,7			No internal connection is made to these pins.
8	Gnd.		Logic ground. Negative supply voltage.
9	Clock		Receiver clock must be phased with digital input such that a positive clock transition occurs near the middle of each received data bit.
10	Encode (Decode)	Low (High)	A single CVSD can provide half-duplex operation. The encode and decode functions are selected by the logic level applied to this input. A low level selects the encode mode, a high level, the decode mode.
11	APT.	Low	Activating this input causes an "alternate plain text" (quieting pattern) to be transmitted without affecting the internal operation of the CVSD.
12	Dig. In		Input for the received digital data.
13	FZ	Low	Activating this input forces the transmitted output, the internal logic, and the recovered audio output into the "quieting" condition.
14	Dig. Out		Output for transmitted digital data.

*Note: No active input should be left in a "floating condition".

©IC MASTER 1978

1. There is one NRZ data bit per clock period. Clock must be phased with digital data such that a positive clock transition occurs in the middle of each received data bit; i.e., the transmitter and receiver clock are in phase.

2. Logic inputs are CMOS compatible at supply voltage and are diode protected. Digital data input is NRZ at clock rate.

3. Logic outputs are CMOS compatible at supply voltage and withstand short-circuits to V_{DD} or ground. Digital data output is NRZ and changes with negative clock transitions.

4. Recommended voice input range for best voice performance.

5. May be used for side-tone in encode mode.

6. Should be externally AC coupled. Presents 100 Kilohms in series with $V_{DD}/2$.

7. Presents 100 Kilohms in series with recovered audio voltage. Zero-signal references is $V_{DD}/2$.

8. Unloaded, for linear signals.

9. Note that filter time constants are inversely proportional to clock rate.

10. Step size compression ratio of the syllabic filter is defined as the ratio of the filter output, with an equal 1-0 bit density input to the filter, to its minimum output.

11. Minimum quantization voltage level expressed as a percentage of supply voltage.

12. The minimum step size between levels is twice the resolution.

13. For large signal amplitudes or high frequencies, the encoder may become slope-overloaded. Figure 1 shows the frequency response at various signal levels,measured with a 3kHz low-pass filter having a 130dB/octave roll-off to -50dB. See Table II.

14. Table I shows the SNR under various conditions, using the output filter described in 13 (above) at a bit rate of 16Kb/s. See Table II.

15. The "quieting" pattern or idle-channel audio output steps at one-half the bit rate, changing state on negative clock transitions.

16. A logic "0" will appear at the AGC output pin when the recovered signal reaches one-half of full-scale value (positive or negative).

17. The recovered signal will be clamped, and the computation will be inhibited, when the recovered signal reaches three-quarters of full-scale value, and will unclamp when it falls below this value (positive or negative).

TABLE I

INPUT FREQUENCY Hz	INPUT AMPLITUDE mV RMS	OUTPUT SNR dB MIN.
300	1400	20
300	45	15
1000	500	14
1000	16	9

YESTERDAY'S RADIO MASTER IS TODAY'S ELECTRONIC DISTRIBUTORS MASTER CATALOG

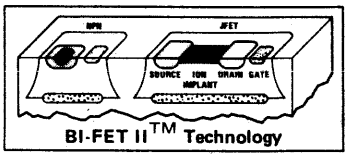
First published to serve you in 1935, The Radio Electronic Master has continuously changed over the years to better meet your needs. Today The Radio Master has become The Electronic Distributors MASTER CATALOG.

The 1978 edition of The Electronic Distributors MASTER CATALOG includes components, systems and subsystems sold through distributors.

It encompasses the following product areas: electronic and electromechanical components, audio and communications equipment, subassembly and panel components, hardware, production equipment and tools, test instrumentation, power sources, wire and cable, and chemicals.

The MASTER CATALOG is divided into four basic sections:

The **GENERAL INDEX** lists manufacturers and products alphabetically, including product cross references. Page numbers are displayed for both manufacturers and products. Manufacturers names are **bold-faced.**



The **MANUFACTURERS' CATALOG SECTION** is a collection of their respective product pages, alphabetically by manufacturer, again including addresses and phone numbers.

The **MANUFACTURERS DIRECTORY** is an alphabetical listing of all manufacturers whose products information is shown. Page numbers are referenced. Sales offices, representatives and distributors are included for many manufacturers.

The **DEALER/DISTRIBUTOR DIRECTORY** geographically lists distribution outlets by state and city. The listings were supplied by manufacturers cataloging in this edition.

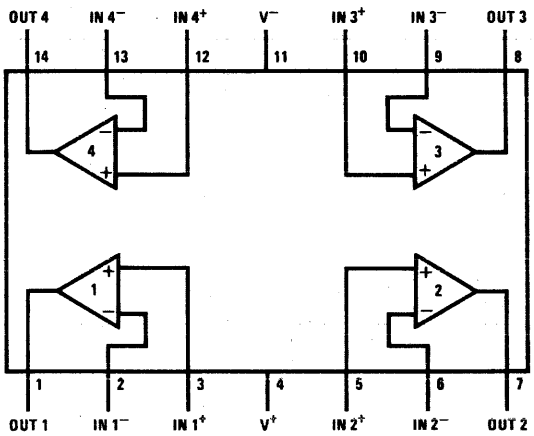
BI-FET II™ Technology

LF347 Wide Bandwidth Quad JFET Input Operational Amplifier

General Description

The LF347 is a low cost high speed quad JFET input operational amplifier with an internally trimmed input offset voltage (BI-FET II™ technology). The device requires a low supply current and yet maintains a large gain bandwidth product and a fast slew rate. In addition, well matched high voltage JFET input devices provide very low input bias and offset currents. The LF347 is pin compatible with the standard LM348.



The LF347 may be used in applications such as high speed integrators, fast D/A converters, sample and hold circuits, active filters and many other circuits requiring low input offset voltage, low input bias current, high input impedance, high slew rate and wide bandwidth. The device has low noise and offset voltage drift.

Features

- Internally trimmed offset voltage — 2 mV
- Low input bias current — 50 pA
- Low input noise voltage — 16 nV/$\sqrt{Hz}$
- Low input noise current — 0.01 pA/$\sqrt{Hz}$
- Wide gain bandwidth — 4 MHz
- High slew rate — 13 V/μs
- Low supply current — 7.2 mA
- High input impedance — $10^{12}\Omega$
- Low total harmonic distortion A_V = 10, R_L = 10k, V_O = 20 Vp-p, BW = 20 Hz–20 kHz — <0.02%
- Low 1/f noise corner — 50 Hz
- Fast settling time to 0.01% — 2 μs

i_n	Equivalent Input Noise Current	T_j = 25°C, f = 1000 Hz		0.01			0.01			0.01		pA/√Hz

Note 1: For operating at elevated temperature, the device must be derated based on a thermal resistance of 125°C/W junction to ambient.

Note 2: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 3: These specifications apply for V_S = ±15V and 0°C ≤ T_A ≤ +70°C. V_{OS}, I_B and I_{OS} are measured at V_{CM} = 0.

Note 4: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_j. Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D. $T_j = T_A + \Theta_{jA} P_D$ where Θ_{jA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 5: Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously in accordance with common practice.

Manufactured under one or more of the following U.S. patents: 3083262, 3189758, 3231797, 3303356, 3317671, 3323071, 3381071, 3408542, 3421025, 3426423, 3440498, 3518750, 3519897, 3557431, 3560765, 3566218, 3571630, 3575609, 3579059, 3593069, 3597640, 3607469, 3617859, 3631312, 3633052, 3638131, 3648071, 3651565, 3693248.

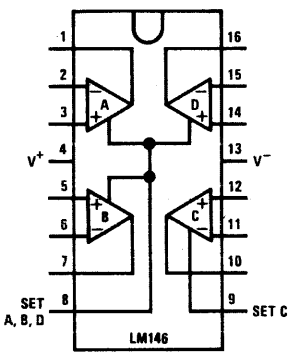
LM146/LM246/LM346
Programmable Quad Operational Amplifiers

General Description



The LM146 series of quad op amps consists of four independent, high gain, internally compensated, low power, programmable amplifiers. Two external resistors (R_{SET}) allow the user to program the gain bandwidth product, slew rate, supply current, input bias current, input offset current and input noise. For example, the user can trade-off supply current for bandwidth or optimize noise figure for a given source resistance. In a similar way, other amplifier characteristics can be tailored to the application. Except for the two programming pins at the end of the package, the LM146 pin-out is the same as the LM124 and LM148.

Features (I_{SET} = 10 μA)

- Programmable electrical characteristics
- Battery-powered operation
- Low supply current — 350 μA amplifier
- Guaranteed gain bandwidth product — 0.8 MHz min
- Large DC voltage gain — 120 dB
- Low noise voltage — 28 nV/√Hz
- Wide power supply range — ±1.5V to ±22V
- Class AB output stage—no crossover distortion
- Ideal pin out for Biquad active filters
- Overload protection for inputs and outputs

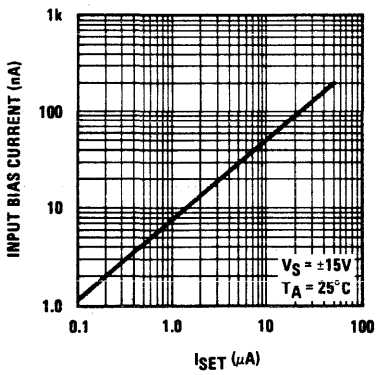
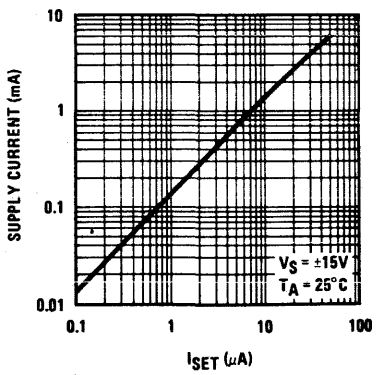
Note 1: For supply voltages less than ±15V, the absolute maximum input voltage is equal to the supply voltage.



Note 2: The maximum power dissipation for these devices must be derated at elevated temperatures and is dictated by T_{jMAX}, θ_{jA}, and the ambient temperature, T_A. The maximum available power dissipation at any temperature is $P_d = (T_{jMAX} - T_A)/\theta_{jA}$ or the 25°C P_{dMAX}, whichever is less.

Note 3: Any of the amplifier outputs can be shorted to ground indefinitely; however, more than one should not be simultaneously shorted as the maximum junction temperature will be exceeded.



Note 4: These specifications apply over the absolute maximum operating temperature range unless otherwise noted.

Application Hints

Avoid reversing the power supply polarity, the device will fail.

Common-Mode Input Voltage: The negative common-mode voltage limit is one diode drop above the negative supply voltage. Exceeding this limit on either input will result in an output phase reversal. The positive common-mode limit is typically 1V below the positive supply voltage. No output phase reversal will occur if this limit is exceeded by either input.

Output Voltage Swing vs I_{SET}: For a desired output voltage swing the value of the minimum load depends on the positive and negative output curent capability of the op amp. The maximum available positive output current, (I_{CL+}), of the device increases with I_{SET} whereas the negative output current (I_{CL-}) is independent of I_{SET}. *Figure 1* illustrates the above.

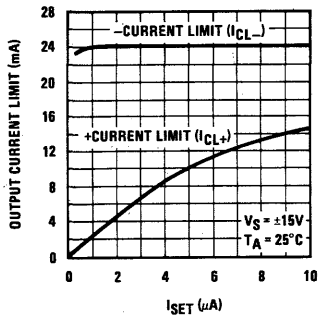

FIGURE 1. Output Current Limit vs I_{SET}

Input Capacitance: The input capacitance, C_{IN}, of the LM146 is approximately 2 pF; any stray capacitance, C_S, (due to external circuit circuit layout) will add to C_{IN}. When resistive or active feedback is applied, an additional pole is added to the open loop frequency response of the device. For instance with resistive feedback *(Figure 2)*, this pole occurs at $1/2\pi$ (R1||R2) (C_{IN} + C_S). Make sure that this pole occurs at least 2 octaves beyond the expected −3 dB frequency corner of the closed loop gain of the amplifier; if not, place a lead capacitor in the feedback such that the time constant of this capacitor and the resistance it parallels is equal to the $R_I(C_S + C_{IN})$, where R_I is the input resistance of the circuit.

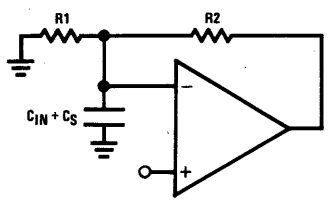

FIGURE 2

Temperature Effect on the GBW: The GBW (gain bandwidth product), of the LM146 is directly proportional to I_{SET} and inversely proportional to the absolute temperature. When using resistors to set the bias current, I_{SET}, of the device, the GBW product will decrease with increasing temperature. Compensation can be provided by creating an I_{SET} current directly proportional to temperature (see typical applications).

Isolation Between Amplifiers: The LM146 die is isothermally layed out such that crosstalk between *all 4* amplifiers is in excess of −105 dB (DC). Optimum isolation (better than −110 dB) occurs between amplifiers A and D, B and C; that is, if amplifier A dissipates power on its output stage, amplifier D is the one which will be affected the least, and vice versa. Same argument holds for amplifiers B and C.

LM146 Typical Performance Summary: The LM146 typical behavior is shown in *Figure 3*. The device is fully predictable. As the set current, I_{SET}, increases, the speed, the bias current, and the supply current increase while the noise power decreases proportionally and the V_{OS} remains constant. The usable GBW range of the op amp is 10 kHz to 3.5–4 MHz.

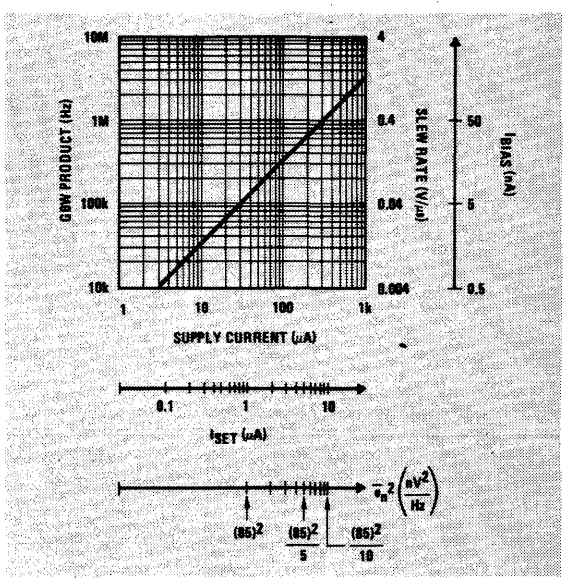

FIGURE 3. LM146 Typical Characteristics

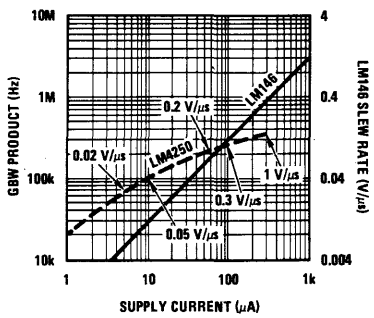
Low Power Supply Operation: The quad op amp operates down to ±1.3V supply. Also, since the internal circuitry is biased through programmable current sources, no degradation of the device speed will occur.

Speed vs Power Consumption: LM146 vs LM4250 (single programmable). Through *Figure 4*, we observe that the LM146's power consumption has been optimized for GBW products above 200 kHz, whereas the LM4250 will reach a GBW of no more than 300 kHz, for GBW products below 200 kHz, the LM4250 will consume less.



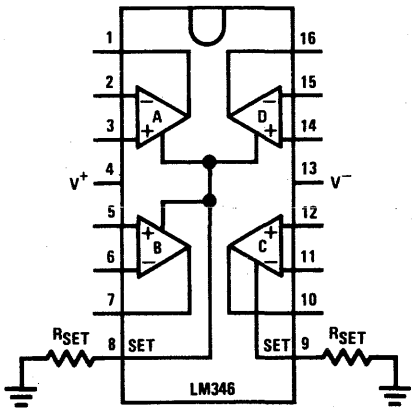


FIGURE 4. LM146 vs LM4250

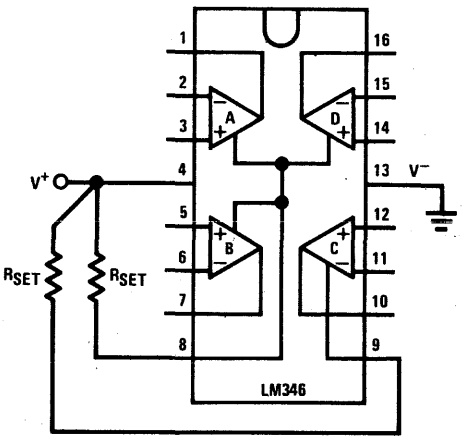
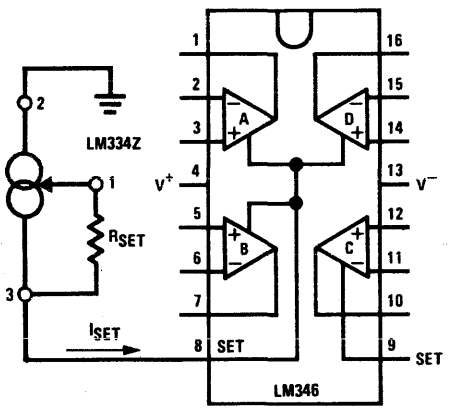


Typical Applications

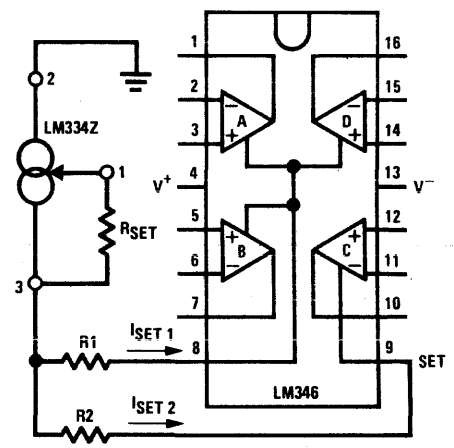
Dual Supply or Negative Supply Biasing



$$I_{SET} \simeq \frac{|V^-| - 0.6V}{R_{SET}}$$

Single (Positive) Supply Biasing

$$I_{SET} \simeq \frac{V^+ - 0.6V}{R_{SET}}$$

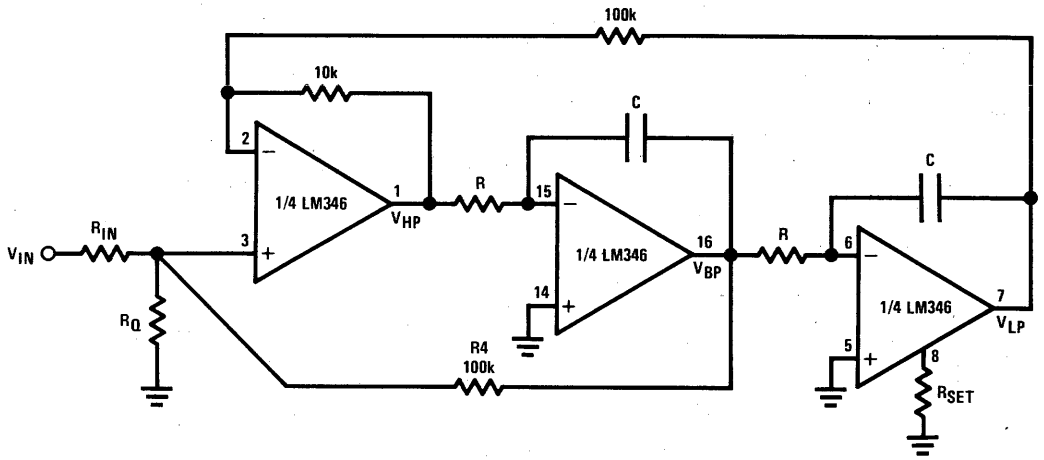


Current Source Biasing with Temperature Compensation

$$I_{SET} = \frac{67.7\ mV}{R_{SET}}$$

- The LM344 provides an I_{SET} directly proportional to absolute temperature. This cancels the slight GBW product temperature coefficient of the LM346.

Biasing all 4 Amplifiers with Single Current Source



$$\frac{I_{SET1}}{I_{SET2}} = \frac{R2}{R1},\ I_{SET1} + I_{SET2} = \frac{67.7\ mV}{R_{SET}}$$

- For $I_{SET1} \simeq I_{SET2}$ resistors R1 and R2 are not required if a slight error between the 2 set currents can be tolerated. If not, then use R1 = R2 to create a 100 mV drop across them.

©IC MASTER 1978

Active Filters Applications

Basic (Non-Inverting "State Variable") Active Filter Building Block

- The LM146 quad programmable op amp is especially suited for active filters because of their adequate GBW product and low power consumption.

  Circuit synthesis equations (for circuit analysis equations, consult with the AF100 and LM148 data sheet).

  Need to know desired: f_o = center frequency measured at the BP output
  Q_o = quality factor measured at the BP output
  H_o = gain at the output of interest (BP or HP or LP or all of them)

  ▲ Relation between different gains: $H_{o(BP)} = 0.316 \times Q_o \times H_{o(LP)}$; $H_{o(LP)} = 10 \times H_{o(HP)}$

  ▲ $R \times C = \dfrac{5.033 \times 10^{-2}}{f_o}$ (sec)

  ▲ For BP output: $R_Q = \left(\dfrac{3.478\, Q_o - H_{o(BP)}}{10^5} - \dfrac{H_{o(BP)}}{10^5 \times 3.478 \times Q_o} \right)^{-1}$; $R_{IN} = \dfrac{\left(\dfrac{3.478\, Q_o}{H_{o(BP)}} - 1 \right)}{\dfrac{1}{R_Q} + 10^{-5}}$

  ▲ For HP output: $R_Q = \dfrac{1.1 \times 10^5}{3.478\, Q_o\, (1.1 - H_{o(HP)}) - H_{o(HP)}}$; $R_{IN} = \dfrac{\dfrac{1.1}{H_{o(HP)}} - 1}{\dfrac{1}{R_Q} + 10^{-5}}$

  Note. All resistor values are given in ohms.

  ▲ For LP output: $R_Q = \dfrac{11 \times 10^5}{3.478\, Q_o\, (11 - H_{o(LP)}) - H_{o(LP)}}$; $R_{IN} = \dfrac{\dfrac{11}{H_{o(LP)}} - 1}{\dfrac{1}{R_Q} + 10^{-5}}$

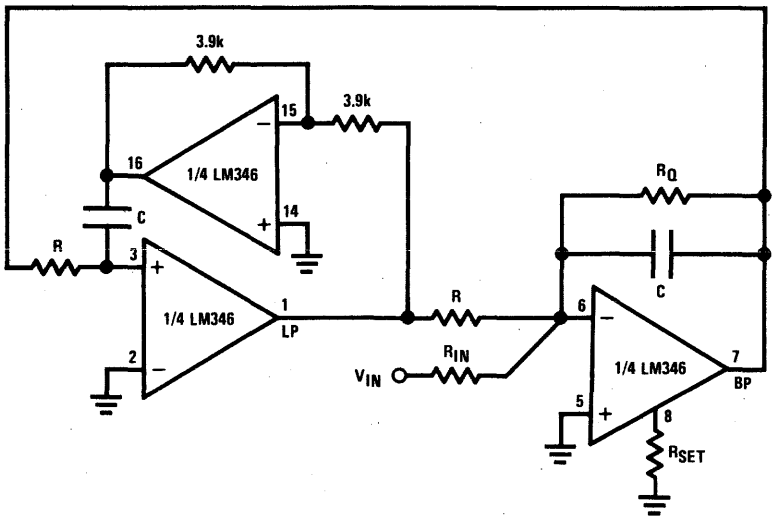
  ▲ For BR (notch) output: Use the 4th amplifier of the LM146 to sum the LP and HP outputs of the basic filter.

$$\sqrt{\frac{R_H}{R_L}} = 0.316\ \frac{f_{notch}}{f_o}$$

Determine R_F according to the desired gains: $H_{o(BR)}\big|_{f << f_{notch}} = \dfrac{R_F}{R_L} H_{o(LP)}$, $H_{o(BR)}\big|_{f >> f_{notch}} = \dfrac{R_F}{R_H} H_{o(HP)}$

- **Where to use amplifier C:** Examine the above gain relations and determine the dynamics of the filter. Do not allow slew rate limiting in any output (V_{HP}, V_{BP}, V_{LP}), that is:

$$V_{IN(peak)} < 63.66 \times 10^3 \times \frac{I_{SET}}{10\,\mu A} \times \frac{1}{f_o \times H_o}\ \text{(Volts)}$$



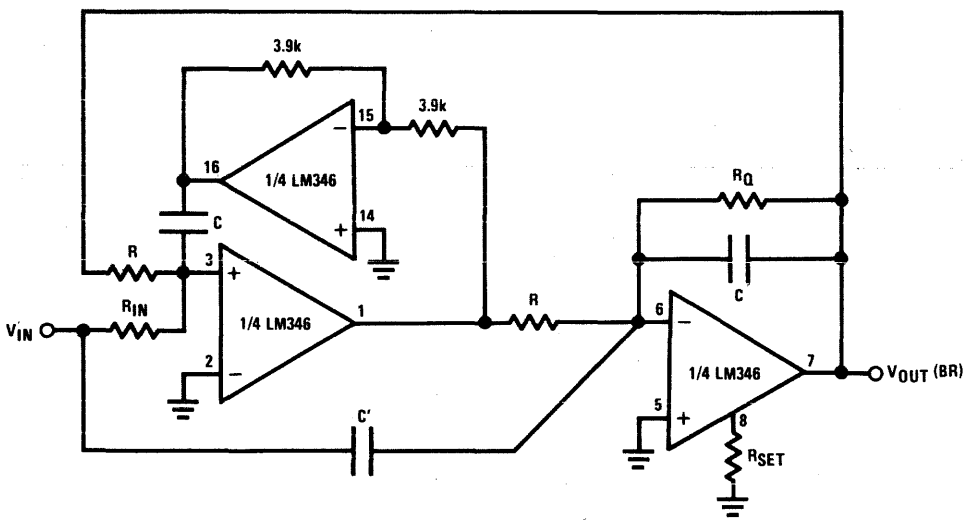
If necessary, use amplifier C, biased at higher I_{SET}, where you get the largest output swing.

Deviation from Theoretical Predictions: Due to the finite GBW products of the op amps the f_o, Q_o will be slightly different from the theoretical predictions.

$$f_{real} \simeq \frac{f_o}{1 + \dfrac{2\, f_o}{GBW}}\ ,\quad Q_{real} \simeq \frac{Q_o}{1 - \dfrac{3.2\, f_o \times Q_o}{GBW}}$$

Active Filters Applications (Continued)

A Simple to Design BP, LP Filter Building Block



- If resistive biasing is used to set the LM346 performance, the Q_o of this filter building block is nearly insensitive to the op amp's GBW product temperature drift; it has also better noise performance than the state variable filter.

Circuit Synthesis Equations

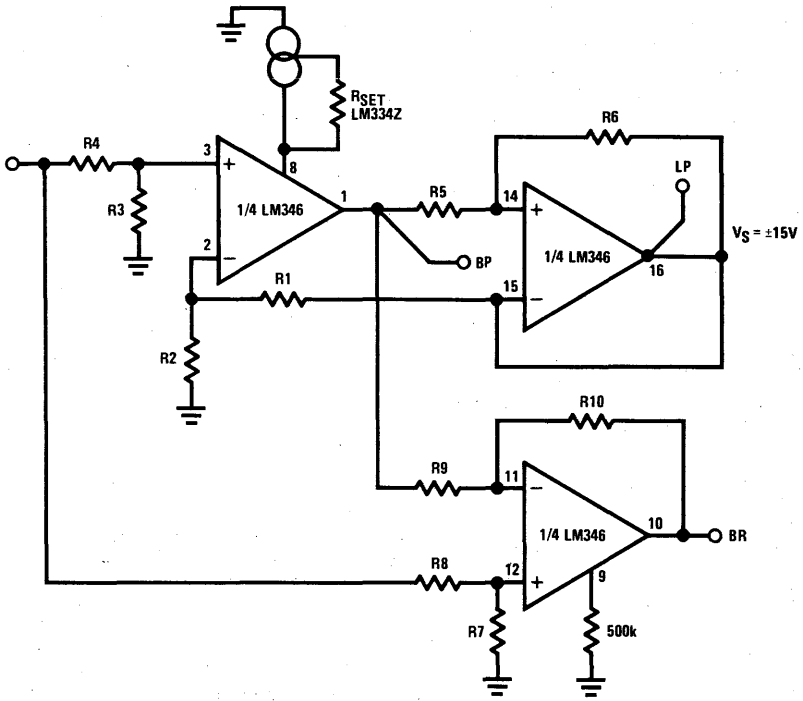
$$H_{o(BP)} = Q_o H_{o(LP)};\ R \times C = \frac{0.159}{f_o};\ R_Q = Q_o \times R;\ R_{IN} = \frac{R_Q}{H_{o(BP)}} = \frac{R}{H_{o(LP)}}$$

- For the eventual use of amplifier C, see comments on the previous page.

A 3-Amplifier Notch Filter (or Elliptic Filter Building Block)

Circuit Synthesis Equations

$$R \times C = \frac{0.159}{f_o};\ R_Q = Q_o \times R;\ R_{IN} = \frac{0.159 \times f_o}{C' \times f^2_{notch}}$$



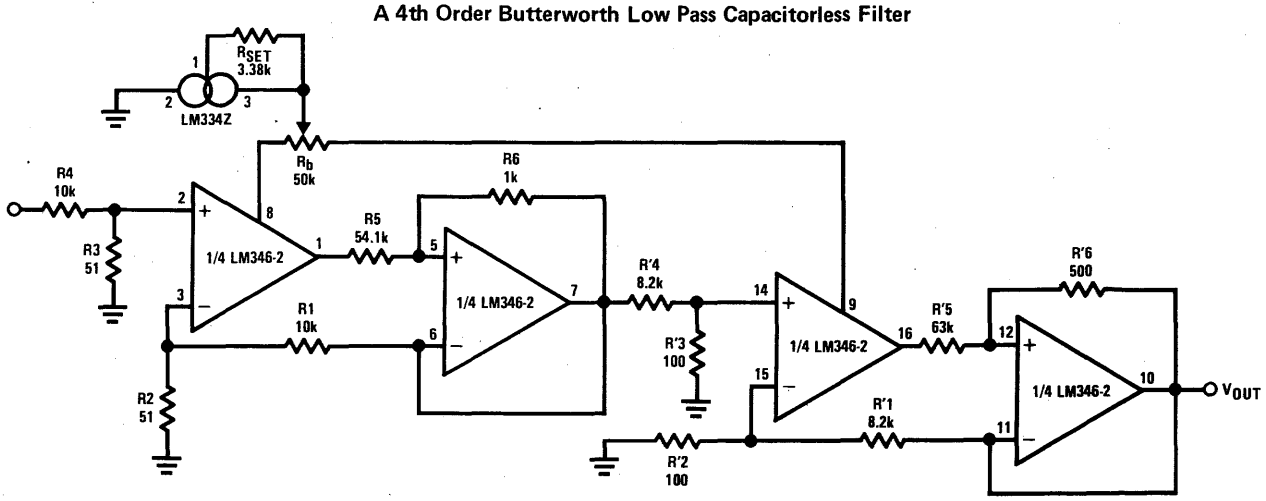
$$H_{o(BR)}\Big|_{f << f_{notch}} = \frac{R}{R_{IN}} H_{o(BR)}\Big|_{f >> f_{notch}} = \frac{C'}{C}$$

- For nothing but a notch output: $R_{IN} = R$, $C' = C$.

©IC MASTER 1978

Active Filters Applications (Continued)

Capacitorless Active Filters (Basic Circuit)

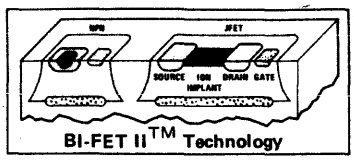


- This is a BP, LP, BR filter. The filter characteristics are created by using the tunable frequency response of the LM346.
- **Limitations:** $Q_o < 10$, $f_o \times Q_o < 1.5$ MHz, output voltage should not exceed $V_{peak(out)} \leq \frac{63.66 \times 10^3}{f_o} \times \frac{I_{SET}\ (\mu A)}{10\ \mu A}$ (V)
- Design equations: $a = \frac{R6 + R5}{R6}$, $b = \frac{R2}{R1 + R2}$, $c = \frac{R3}{R3 + R4}$, $d = \frac{R7}{R8 + R7}$, $e = \frac{R10}{R9 + R10}$, $f_{o(BP)} = f_u \sqrt{\frac{b}{a}}$, $H_{o(BP)} = a \times c$,

  $H_{o(LP)} = \frac{c}{b}$, $Q_o = \sqrt{a \times b}$

  $f_{o(BR)} = f_{o(BP)} \left(1 - \frac{c}{b}\right) \simeq f_{o(BP)}$ $(C << 1)$ provided that $d = H_{o(BP)} \times e$, $H_{o(BR)} = \frac{R10}{R9}$.
- Advantage: f_o, Q_o, H_o can be independently adjusted; that is, the filter is extremely easy to tune.
- Tuning procedure (ex. BP tuning)
  1. Pick up a convenient value for b; $(b < 1)$
  2. Adjust Q_o through R5
  3. Adjust $H_{o(BP)}$ through R4
  4. Adjust f_o through R_{SET}

A 4th Order Butterworth Low Pass Capacitorless Filter



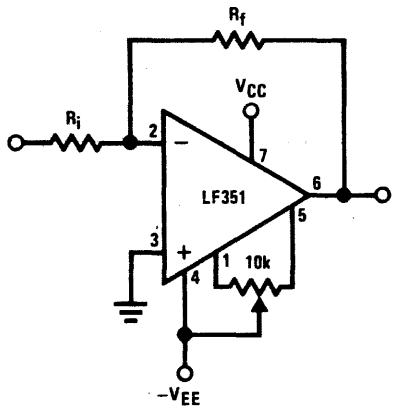
Ex: $f_c = 20$ kHz, H_o (gain of the filter) = 1, $Q_{o1} = 0.541$, $Q_{o2} = 1.306$.

- Since for this filter the GBW product of all 4 amplifiers has been designed to be the same (~1 MHz) only one current source can be used to bias the circuit. Fine tuning can be further accomplished through R_b.

National Semiconductor

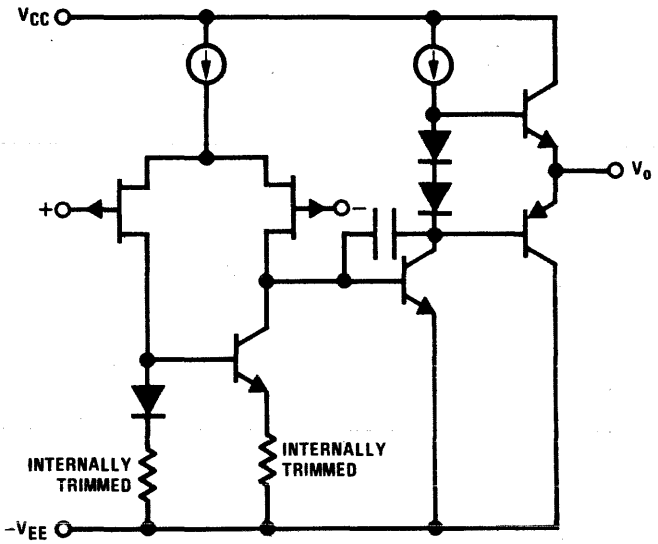
LF351 Wide Bandwidth JFET Input Operational Amplifiers

General Description



The LF351 is a low cost high speed JFET input operational amplifier with an internally trimmed input offset voltage (BI-FET II™ technology). The device requires a low supply current and yet maintains a large gain bandwidth product and a fast slew rate. In addition, well matched high voltage JFET input devices provide very low input bias and offset currents. The LF351 is pin compatible with the standard LM741 and uses the same offset voltage adjustment circuitry. This feature allows designers to immediately upgrade the overall performance of existing LM741 designs.

The LF351 may be used in applications such as high speed integrators, fast D/A converters, sample-and-hold circuits and many other circuits requiring low input offset voltage, low input bias current, high input impedance, high slew rate and wide bandwidth. The device has low noise and offset voltage drift, but for applications where these requirements are critical, the LF356 is recommended. If maximum supply current is important, however, the LF351 is the better choice.



Features

- Internally trimmed offset voltage — 2 mV
- Low input bias current — 50 pA
- Low input noise voltage — 16 nV/$\sqrt{Hz}$
- Low input noise current — 0.01 pA/$\sqrt{Hz}$
- Wide gain bandwidth — 4 MHz
- High slew rate — 13 V/μs
- Low supply current — 1.8 mA
- High input impedance — $10^{12}\Omega$
- Low total harmonic distortion A_V = 10, R_L = 10k, V_O = 20 Vp-p, BW = 20 Hz–20 kHz — <0.02%
- Low 1/f noise corner — 50 Hz
- Fast settling time to 0.01% — 2 μs

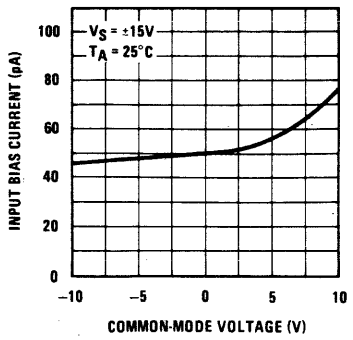
e_n	Equivalent Input Noise Voltage	T_A = 25°C, R_S = 100Ω, f = 1000 Hz		16			16			16		$nV/\sqrt{Hz}$
i_n	Equivalent Input Noise Current	T_j = 25°C, f = 1000 Hz		0.01			0.01			0.01		$pA/\sqrt{Hz}$

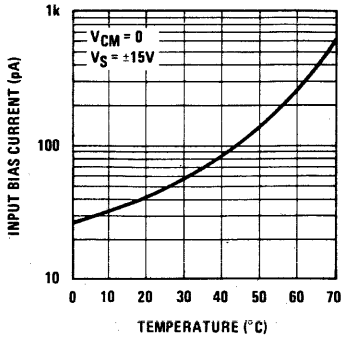
Note 1: For operating at elevated temperature, the device must be derated based on a thermal resistance of 150°C/W junction to ambient or 45°C/W junction to case.

Note 2: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.



Note 3: These specifications apply for V_S = ±15V and 0°C ≤ T_A ≤ +70°C. V_{OS}, I_B and I_{OS} are measured at V_{CM} = 0.

Note 4: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_j. Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D. $T_j = T_A + \Theta_{jA} P_D$ where Θ_{jA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.



Note 5: Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously in accordance with common practice.

Application Hints

The LF351 is an op amp with an internally trimmed input offset voltage and JFET input devices (BI-FET II™). These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore, large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will cause a reversal of the phase to the output and force the amplifier output to the corresponding high or low state. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a

©IC MASTER 1978

Application Hints (Continued)

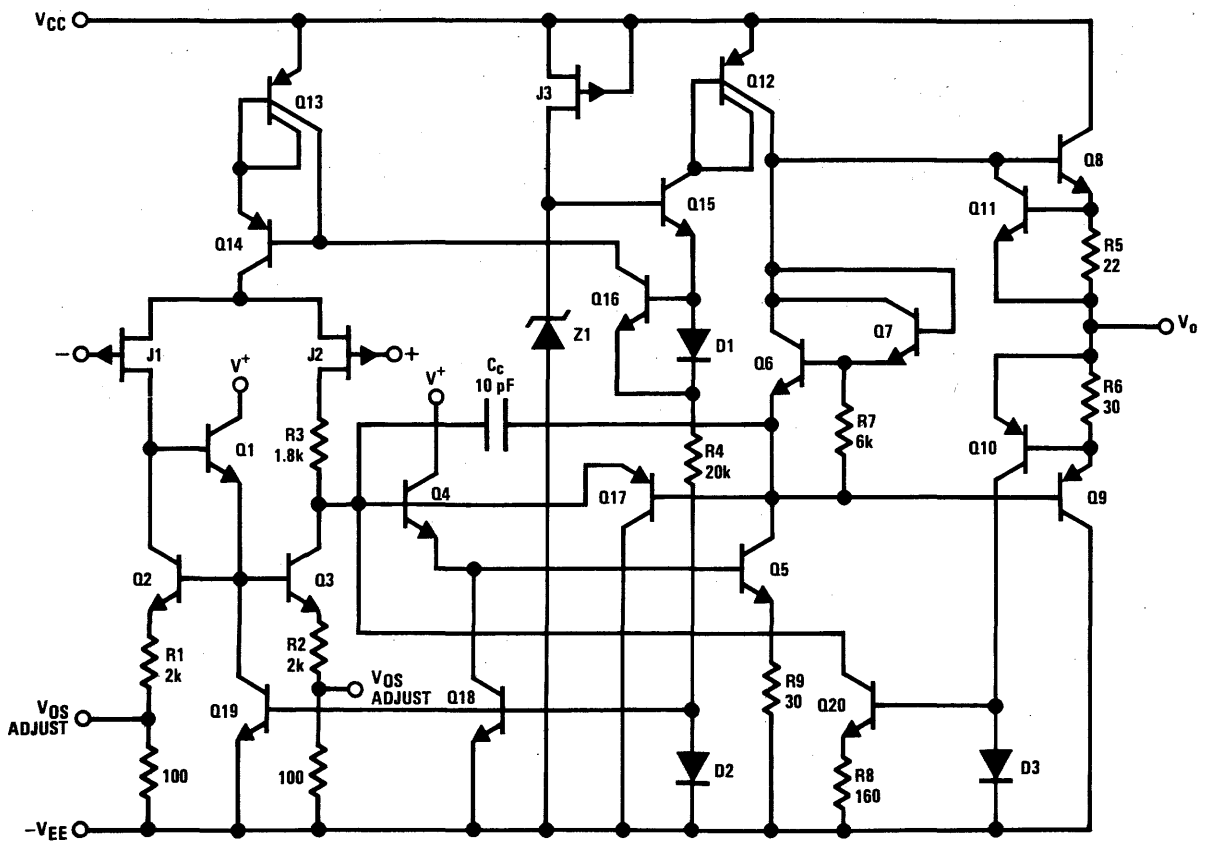
high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output; however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

The amplifier will operate with a common-mode input voltage equal to the positive supply; however, the gain bandwidth and slew rate may be decreased in this condition. When the negative common-mode voltage swings to within 3V of the negative supply, an increase in input offset voltage may occur.

The LF351 is biased by a zener reference which allows normal circuit operation on ±4V power supplies. Supply voltages less than these may result in lower gain bandwidth and slew rate.

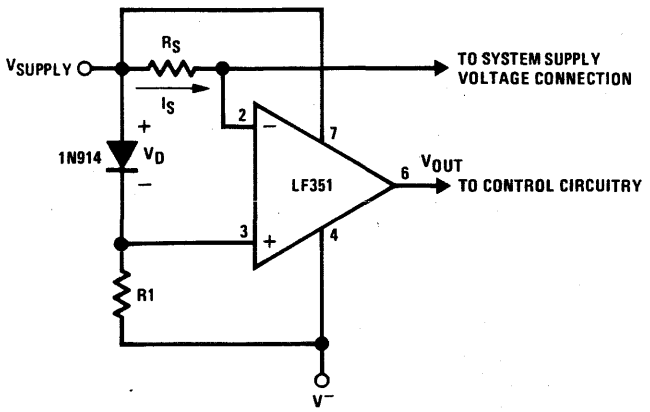
The LF351 will drive a 2 kΩ load resistance to ±10V over the full temperature range of 0°C to +70°C. If the amplifier is forced to drive heavier load currents, however, an increase in input offset voltage may occur on the negative voltage swing and finally reach an active current limit on both positive and negative swings.



Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

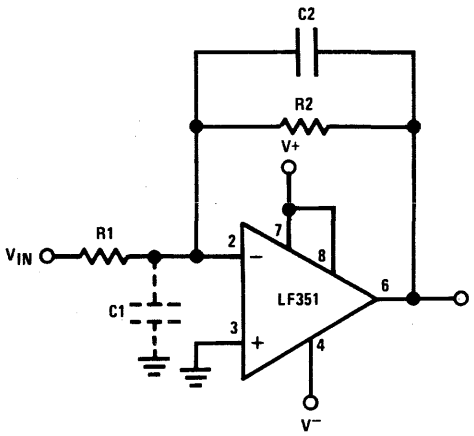
Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.



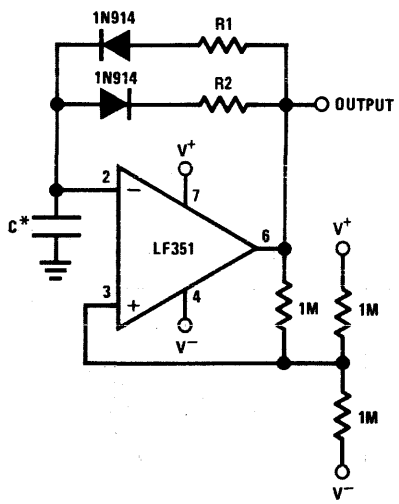
A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to AC ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately 6 times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

Detailed Schematic



Typical Applications

Supply Current Indicator/Limiter

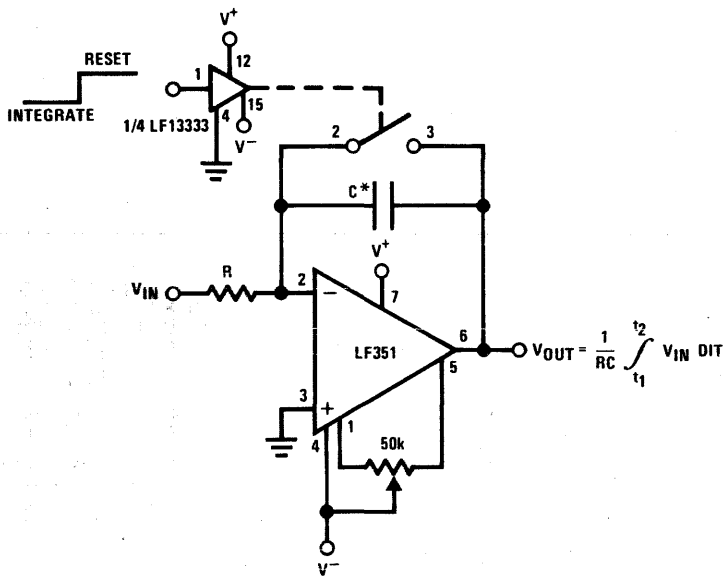


- V_{OUT} switches high when $R_S I_S > V_D$

Hi-Z_{IN} Inverting Amplifier

Parasitic input capacitance C1 ≅ (3 pF for LF351 plus any additional layout capacitance) interacts with feedback elements and creates undesirable high frequency pole. To compensate, add C2 such that: R2C2 ≅ R1C1.

Ultra-Low (or High) Duty Cycle Pulse Generator



- $t_{OUTPUT\ HIGH} \approx R1C \ln \frac{4.8 - 2V_S}{4.8 - V_S}$
- $t_{OUTPUT\ LOW} \approx R2C \ln \frac{2V_S - 7.8}{V_S - 7.8}$

where $V_S = V^+ + |V^-|$

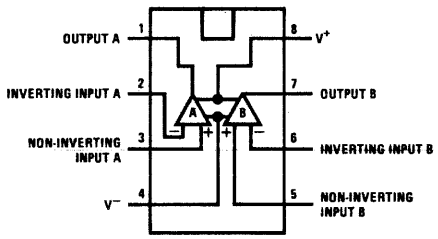
LF353 Wide Bandwidth Dual JFET Input Operational Amplifier

General Description

The LF353 is a low cost high speed dual JFET input operational amplifier with an internally trimmed input offset voltage (BI-FET II™ technology). The device requires a low supply current and yet maintains a large gain bandwidth product and a fast slew rate. In addition, well matched high voltage JFET input devices provide very low input bias and offset currents. The LF353 is pin compatible with the standard LM1558.



The LF353 may be used in applications such as high speed integrators, fast D/A converters, sample and hold circuits and many other circuits requiring low input offset voltage, low input bias current, high input impedance, high slew rate and wide bandwidth. The device has low noise and offset voltage drift.

Features

- Internally trimmed offset voltage — 2 mV
- Low input bias current — 50 pA
- Low input noise voltage — 16 nV/$\sqrt{Hz}$
- Low input noise current — 0.01 pA/$\sqrt{Hz}$
- Wide gain bandwidth — 4 MHz
- High slew rate — 13 V/μs
- Low supply current — 3.6 mA
- High input impedance — $10^{12}\Omega$
- Low total harmonic distortion A_V = 10, R_L = 10k, V_O = 20 Vp-p, BW = 20 Hz–20 kHz — <0.02%
- Low 1/f noise corner — 50 Hz
- Fast settling time to 0.01% — 2 μs

BI-FET Technology

LF155/LF156/LF157 Monolithic JFET Input Operational Amplifiers

LF155, LF155A, LF255, LF355, LF355A, LF355B low supply current
LF156, LF156A, LF256, LF356, LF356A, LF356B wide band
LF157, LF157A, LF257, LF357, LF357A, LF357B wide band decompensated ($A_{V_{MIN}}$ = 5)

General Description

These are the first monolithic JFET input operational amplifiers to incorporate well matched, high voltage JFETs on the same chip with standard bipolar transistors (BI-FET Technology). These amplifiers feature low input bias and offset currents, low offset voltage and offset voltage drift, coupled with offset adjust which does not degrade drift or common-mode rejection. The devices are also designed for high slew rate, wide bandwidth, extremely fast settling time, low voltage and current noise and a low 1/f noise corner.

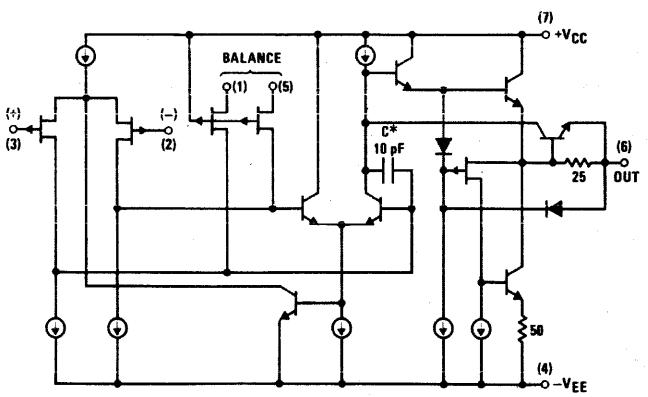
Advantages

- Replace expensive hybrid and module FET op amps
- Rugged JFETs allow blow-out free handling compared with MOSFET input devices
- Excellent for low noise applications using either high or low source impedance—very low 1/f corner
- Offset adjust does not degrade drift or common-mode rejection as in most monolithic amplifiers
- New output stage allows use of large capacitive loads (10,000 pF) without stability problems
- Internal compensation and large differential input voltage capability

Applications

- Precision high speed integrators
- Fast D/A and A/D converters
- High impedance buffers
- Wideband, low noise, low drift amplifiers
- Logarithmic amplifiers
- Photocell amplifiers
- Sample and Hold circuits

Common Features



(LF155A, LF156A, LF157A)

- Low input bias current — 30 pA
- Low Input Offset Current — 3 pA
- High input impedance — $10^{12}\Omega$
- Low input offset voltage — 1 mV
- Low input offset voltage temperature drift — 3μV/°C
- Low input noise current — 0.01 pA/√Hz
- High common-mode rejection ratio — 100 dB
- Large dc voltage gain — 106 dB

Uncommon Features

	LF155A	LF156A	LF157A (A_V = 5)*	UNITS
■ Extremely fast settling time to 0.01%	4	1.5	1.5	μs
■ Fast slew rate	5	12	50	V/μs
■ Wide gain bandwidth	2.5	5	20	MHz
■ Low input noise voltage	20	12	12	nV/√Hz

Notes for Electrical Characteristics

Note 1: The maximum power dissipation for these devices must be derated at elevated temperatures and is dictated by T_{jMAX}, θ_{jA}, and the ambient temperature, T_A. The maximum available power dissipation at any temperature is $P_d = (T_{jMAX} - T_A)/\theta_{jA}$ or the 25°C P_{dMAX}, whichever is less.

Note 2: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

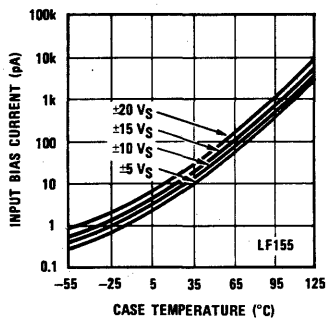
Note 3: Unless otherwise stated, these test conditions apply:

	LF155A/6A/7A LF155/6/7	LF255/6/7	LF355A/6A/7A	LF355B/6B/7B	LF355/6/7
Supply Voltage, V_S	$\pm15V \le V_S \le \pm20V$	$\pm15V \le V_S \le \pm20V$	$\pm15V \le V_S \le \pm18V$	$\pm15V \le V_S \pm20V$	$V_S = \pm15V$
T_A	$-55°C \le T_A \le +125°C$	$-25°C \le T_A \le +85°C$	$0°C \le T_A \le +70°C$	$0°C \le T_A \le +70°C$	$0°C \le T_A \le +70°C$
T_{HIGH}	+125°C	+85°C	+70°C	+70°C	+70°C

and V_{OS}, I_B and I_{OS} are measured at $V_{CM} = 0$.

Note 4: The Temperature Coefficient of the adjusted input offset voltage changes only a small amount (0.5μV/°C typically) for each mV of adjustment from its original unadjusted value. Common-mode rejection and open loop voltage gain are also unaffected by offset adjustment.

Note 5: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_J. Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, Pd. $T_j = T_A + \Theta_{jA}$ Pd where Θ_{jA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.



Note 6: Supply Voltage Rejection is measured for both supply magnitudes increasing or decreasing simultaneously, in accordance with common practice.

Note 7: Settling time is defined here, for a unity gain inverter connection using 2 kΩ resistors for the LF155/6. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within 0.01% of its final value from the time a 10V step input is applied to the inverter. For the LF157, $A_V = -5$, the feedback resistor from output to input is 2 kΩ and the output step is 10V (See Settling Time Test Circuit, page 9).

Application Hints

The LF155/6/7 series are op amps with JFET input devices. These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore large differential input voltages can easily be accomodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

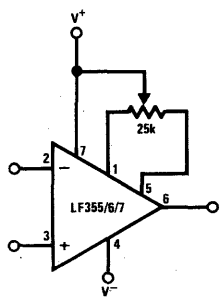
Exceeding the negative common-mode limit on either input will cause a reversal of the phase to the output and force the amplifier output to the corresponding high or low state. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

These amplifiers will operate with the common-mode input voltage equal to the positive supply. In fact, the common-mode voltage can exceed the positive supply by approximately 100 mV independent of supply voltage and over the full operating temperature range. The positive supply can therefore be used as a reference on an input as, for example, in a supply current monitor and/or limiter.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

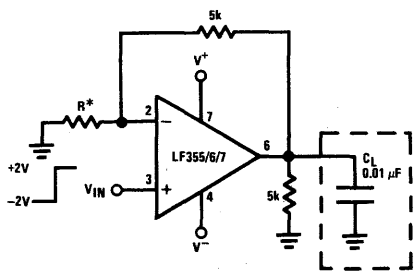
Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.



All of the bias currents in these amplifiers are set by FET current sources. The drain currents for the amplifiers are therefore essentially independent of supply voltage.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pickup" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to ac ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

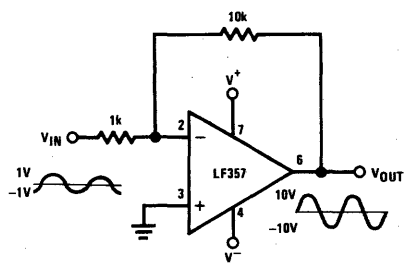


Typical Circuit Connections

V_{OS} Adjustment

- V_{OS} is adjusted with a 25k potentiometer
- The potentiometer wiper is connected to V^+
- For potentiometers with temperature coefficient of 100 ppm/°C or less the additional drift with adjust is ≈ 0.5 μV/°C/mV of adjustment
- Typical overall drift: 5 μV/°C ±(0.5 μV/°C/mV of adj.)

Driving Capacitive Loads

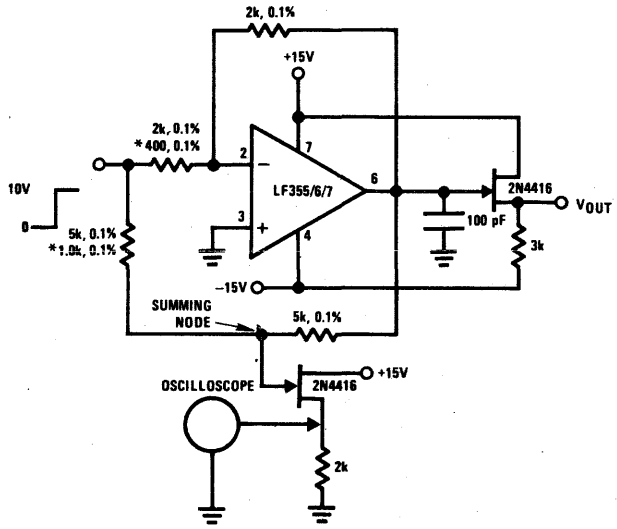


*LF155/6 R = 5k
LF157 R = 1.25k

Due to a unique output stage design, these amplifiers have the ability to drive large capacitive loads and still maintain stability. $C_{L(MAX)} \cong 0.01\ \mu F$.

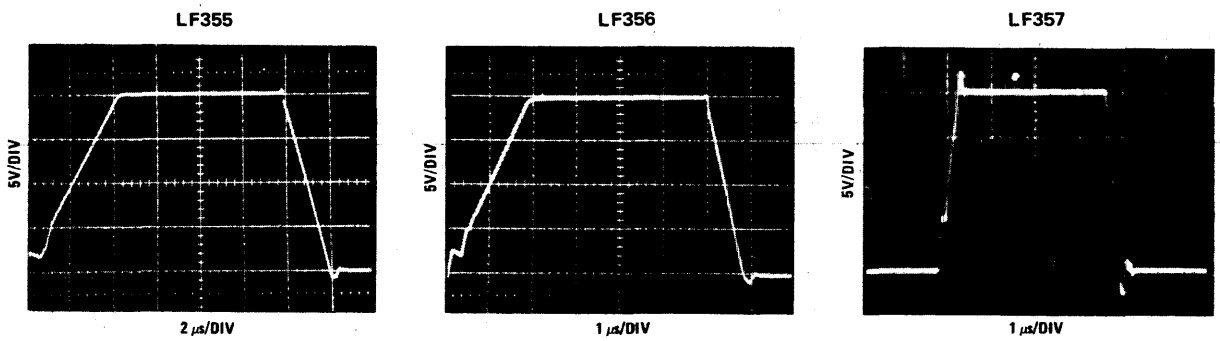
Overshoot ≤ 20%

Settling time (t_s) ≅ 5 μs



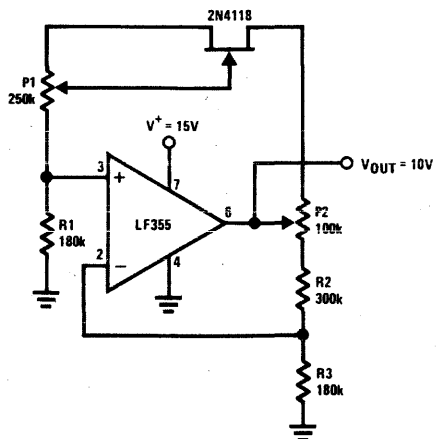
LF157. A Large Power BW Amplifier

For distortion ≤ 1% and a 20 Vp-p V_{OUT} swing, power bandwidth is: 500 kHz.



Typical Applications

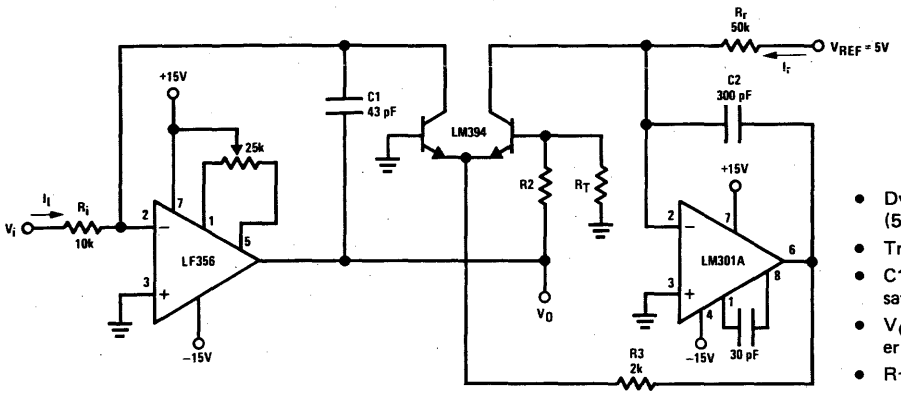
Settling Time Test Circuit



- Settling time is tested with the LF155/6 connected as unity gain inverter and LF157 connected for $A_V = -5$
- FET used to isolate the probe capacitance
- Output = 10V step
- $A_V = -5$ for LF157

Large Signal Inverter Output, V_{OUT} (from Settling Time Circuit)

Low Drift Adjustable Voltage Reference

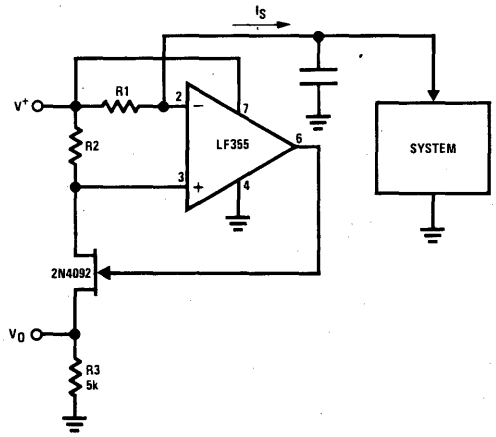


- $\Delta V_{OUT}/\Delta T = \pm 0.002\%/°C$
- All resistors and potentiometers should be wire-wound
- P1: drift adjust
- P2: V_{OUT} adjust
- Use LF155 for
  - ▲ Low I_B
  - ▲ Low drift
  - ▲ Low supply current

©IC MASTER 1978

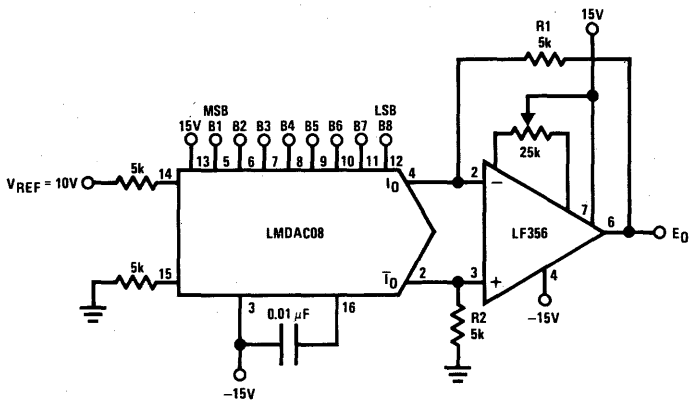
Typical Applications (Continued)

Fast Logarithmic Converter



- Dynamic range: 100 μA ≤ I_i ≤ 1 mA (5 decades), $|V_O|$ = 1V/decade
- Transient response: 3 μs for ΔI_i = 1 decade
- C1, C2, R2, R3: added dynamic compensation
- V_{OS} adjust the LF156 to minimize quiescent error
- R_T: Tel Labs type Q81 + 0.3%/°C

$$|V_{OUT}| = \left[1 + \frac{R2}{R_T}\right] \frac{kT}{q} \ln V_i \left[\frac{R_r}{V_{REF}\, R_i}\right] = \log V_i \frac{1}{R_i\, I_r}$$

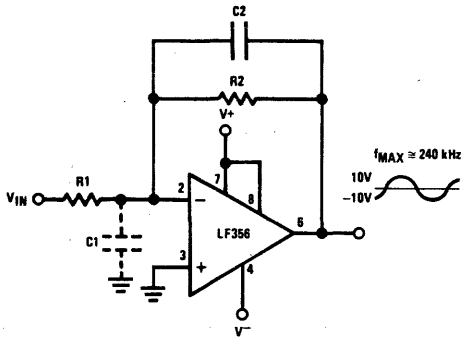


R2 = 15.7k, R_T = 1k, 0.3%/°C (for temperature compensation)

Precision Current Monitor

- V_O = 5 R1/R2 (V/mA of I_S)
- R1, R2, R3: 0.1% resistors
- Use LF155 for
  - Common-mode range to supply range
  - Low I_B
  - Low V_{OS}
  - Low supply current

8-Bit D/A Converter with Symmetrical Offset Binary Operation



- R1, R2 should be matched within ±0.05%
- Full-scale response time: 3 μs

E_O	B1	B2	B3	B4	B5	B6	B7	B8	COMMENTS
+9.920	1	1	1	1	1	1	1	1	Positive Full-Scale

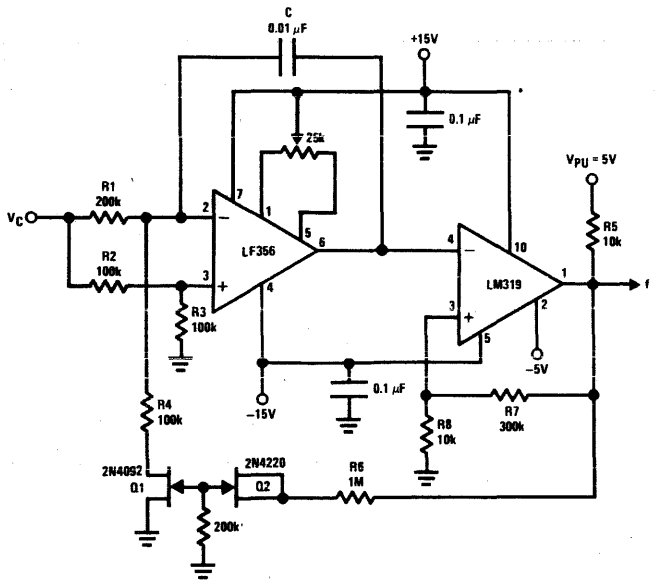
Typical Applications (Continued)

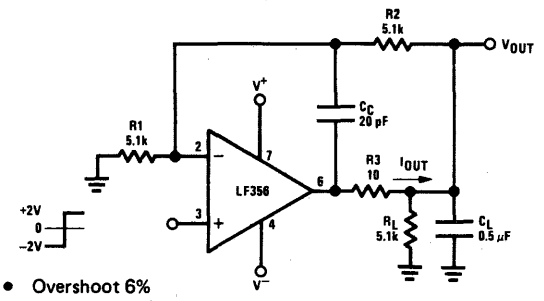
Wide BW Low Noise, Low Drift Amplifier



- Power BW: $f_{MAX} = \frac{S_r}{2\pi V_P} \cong 240$ kHz
- Parasitic input capacitance C1 ≅ (3 pF for LF155, LF156 and LF157 plus any additional layout capacitance) interacts with feedback elements and creates undesirable high frequency pole. To compensate add C2 such that: R2C2 ≅ R1C1.

Boosting the LF156 with a Current Amplifier

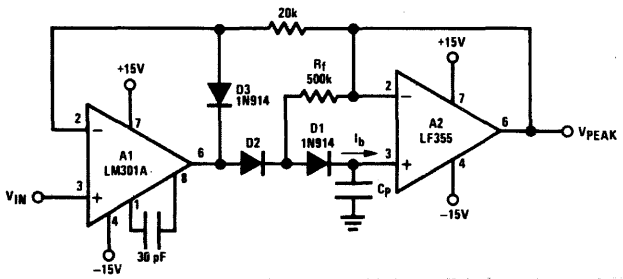
- $I_{OUT(MAX)} \cong 150$ mA (will drive $R_L \geq 100\Omega$)
- $\frac{\Delta V_{OUT}}{\Delta T} = \frac{0.15}{10^{-2}}$ V/μs (with C_L shown)
- No additional phase shift added by the current amplifier



3 Decades VCO

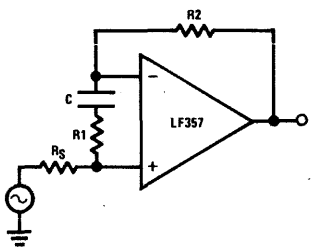
$$f = \frac{V_C\,(R8+R7)}{[8\,V_{PU}\,R8\,R1]\,C}, \quad 0 \leq V_C \leq 30V,\ 10\text{ Hz} \leq f \leq 10\text{ kHz}$$

R1, R4 matched. Linearity 0.1% over 2 decades.



Isolating Large Capacitive Loads

- Overshoot 6%
- t_s 10 μs
- When driving large C_L, the V_{OUT} slew rate determined by C_L and $I_{OUT(MAX)}$:

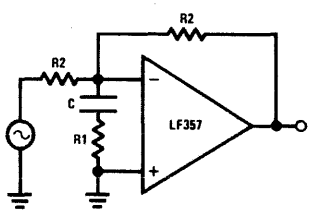


$$\frac{\Delta V_{OUT}}{\Delta T} = \frac{I_{OUT}}{C_L} \cong \frac{0.02}{0.5}\ \text{V/μs} = 0.04\ \text{V/μs (with } C_L \text{ shown)}$$

Low Drift Peak Detector

- By adding D1 and R_f, V_{D1} = 0 during hold mode. Leakage of D2 provided by feedback path through R_f.
- Leakage of circuit is essentially I_b (LF155, LF156) plus capacitor leakage of C_P.
- Diode D3 clamps V_{OUT} (A1) to $V_{IN}-V_{D3}$ to improve speed and to limit reverse bias of D2.
- Maximum input frequency should be $<< 1/2\pi R_f C_{D2}$ where C_{D2} is the shunt capacitance of D2.

Non-Inverting Unity Gain Operation for LF157



$$R1C \geq \frac{1}{(2\pi)\ (5\text{ MHz})}$$

$$R1 = \frac{R2 + R_S}{4}$$

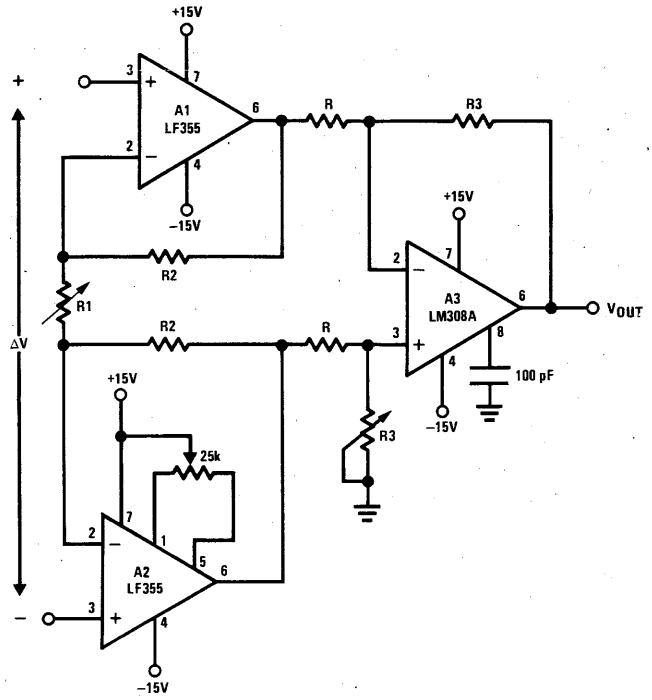
$A_{V(DC)} = 1$

$f_{-3\text{ dB}} \approx 5$ MHz

Inverting Unity Gain for LF157

$$R1C \geq \frac{1}{(2\pi)\ (5\text{ MHz})}$$

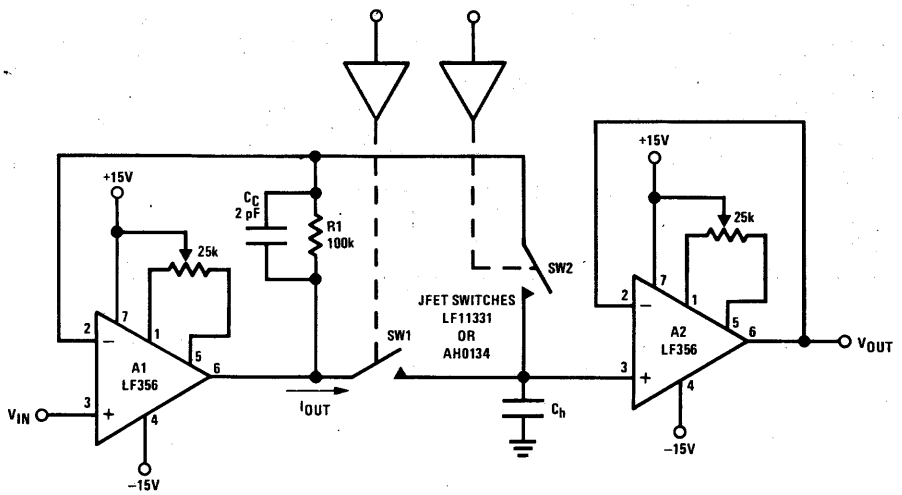
$$R1 = \frac{R2}{4}$$



$A_{V(DC)} = -1$

$f_{-3\text{ dB}} \approx 5$ MHz

©IC MASTER 1978



Typical Applications (Continued)

High Impedance, Low Drift Instrumentation Amplifier

- $V_{OUT} = \frac{R3}{R}\left[\frac{2R2}{R1} + 1\right] \Delta V, V^- + 2V \leq V_{IN}$ common-mode $\leq V^+$
- System V_{OS} adjusted via A2 V_{OS} adjust
- Trim R3 to boost up CMRR to 120 dB. Instrumentation amplifier Resistor array RA201 (National Semiconductor) recommended

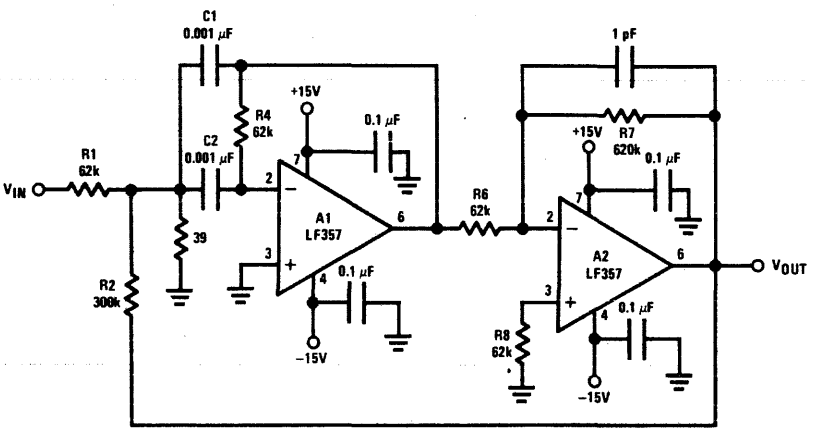
Fast Sample and Hold

- Both amplifiers (A1, A2) have feedback loops individually closed with stable responses (overshoot negligible)
- Acquisition time T_A, estimated by:

  $T_A \cong \left[\frac{2R_{ON} \cdot V_{IN} \cdot C_h}{S_r}\right]^{1/2}$ provided that:

  $V_{IN} < 2\pi S_r R_{ON} C_h$ and $T_A > \frac{V_{IN} C_h}{I_{OUT(MAX)}}$, R_{ON} is of SW1

  If inequality not satisfied: $T_A \cong \frac{V_{IN} C_h}{20\ mA}$
- LF156 developes full S_r output capability for $V_{IN} \geq 1V$
- Addition of SW2 improves accuracy by putting the voltage drop across SW1 inside the feedback loop
- Overall accuracy of system determined by the accuracy of both amplifiers, A1 and A2

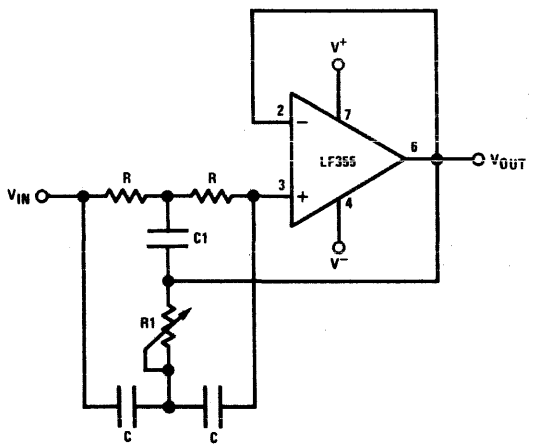


Typical Applications (Continued)

High Accuracy Sample and Hold

- By closing the loop through A2, the V_{OUT} accuracy will be determined uniquely by A1. No V_{OS} adjust required for A2.
- T_A can be estimated by same considerations as previously but, because of the added propagation delay in the feedback loop (A2) the overshoot is not negligible.
- Overall system slower than fast sample and hold
- R1, C_C: additional compensation
- Use LF156 for
  - ▲ Fast settling time
  - ▲ Low V_{OS}

High Q Band Pass Filter



- By adding positive feedback (R2) Q increases to 40
- f_{BP} = 100 kHz

$$\frac{V_{OUT}}{V_{IN}} = 10\sqrt{Q}$$

- Clean layout recommended
- Response to a 1 Vp-p tone burst: 300 μs

High Q Notch Filter

- 2R1 = R = 10 MΩ
  2C = C1 = 300 pF
- Capacitors should be matched to obtain high Q
- f_{NOTCH} = 120 Hz, notch = −55 dB, Q > 100
- Use LF155 for
  - ▲ Low I_B
  - ▲ Low supply current

©IC MASTER 1978

Definition of Terms

Input Offset Voltage: That voltage which must be applied between the input terminals through two equal resistances to obtain zero output voltage.

Input Offset Current: The difference in the currents into the two input terminals when the output is at zero.

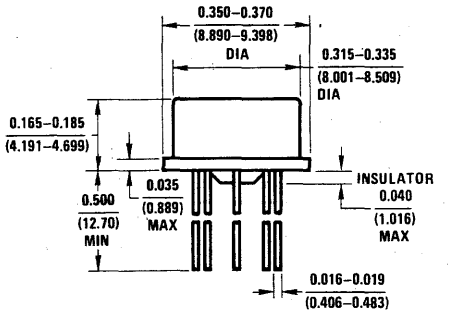
Input Bias Current: The average of the two input currents.

Input Common-Mode Voltage Range: The range of voltages on the input terminals for which the amplifier is operational. Note that the specifications are not guaranteed over the full common-mode voltage range unless specifically stated.

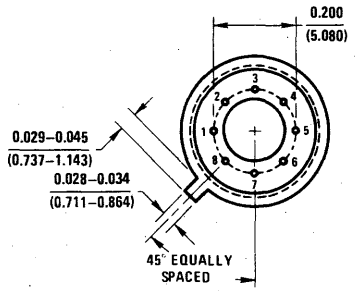
Common-Mode Rejection Ratio: The ratio of the input common-mode voltage range to the peak-to-peak change in input offset voltage over this range.

Input Resistance: The ratio of the change in input voltage to the change in input current on either input with the other grounded.

Supply Current: The current required from the power supply to operate the amplifier with no load and the output midway between the supplies.



Output Voltage Swing: The peak output voltage swing, referred to zero, that can be obtained without clipping.



Large-Signal Voltage Gain: The ratio of the output voltage swing to the change in input voltage required to drive the output from zero to this voltage.

Power Supply Rejection Ratio: The ratio of the change in input offset voltage to the change in power supply voltage producing it. The typical curves in this sheet show values for each supply independently changed. The electrical specification, however, is measured for both supply magnitudes increasing or decreasing simultaneously, in accordance with common practice.

Settling Time: The time required for the error between input and output to settle to within a specified limit after an input is applied to the test circuit shown in typical applications.

National Semiconductor

LFT155/LFT156, LFT355/LFT356 Low Offset Monolithic JFET Input Operational Amplifiers

General Description

These monolithic JFET input operational amplifiers have guaranteed low offset voltage and offset voltage drift along with high common-mode rejection which allows their use in applications requiring precision to 0.01%. In addition, they have the same low bias and offset currents, high slew rate, wide bandwidth, extremely fast settling time, low voltage and current noise and low 1/f corner as do the normal LF155/LF156 BI-FET operational amplifier families.

Advantages

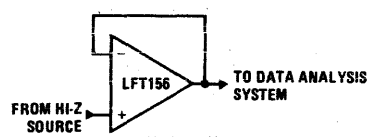
- Ultra-low offset—12-bit accuracy without adjust
- Rugged JFETs allow blow-out free handling compared with MOSFET input devices
- Excellent for low noise applications using either high or low source impedance—very low 1/f corner
- Offset adjust does not degrade drift or common-mode rejection as in most monolithic amplifiers
- New output stage allows use of large capacitive loads (10,000 pF) without stability problems
- Internal compensation and large differential input voltage capability

Applications

- Output amplifiers in 10 and 12-bit current mode D/A converters
- Data acquisition front-end amplifiers: (DC coupled difference amplifier, buffer)
- Output buffer in S/H circuits
- Low pass filters with DC gain
- Amplifier for auto-zeroing loops
- Long time integrators
- Precise analog computer amplifiers and integrators
- Replace op amps in existing systems requiring:
  - Offset voltage adjustment
  - Drift selection
  - Fast settling
  - Low noise
  - Low bias current

Features

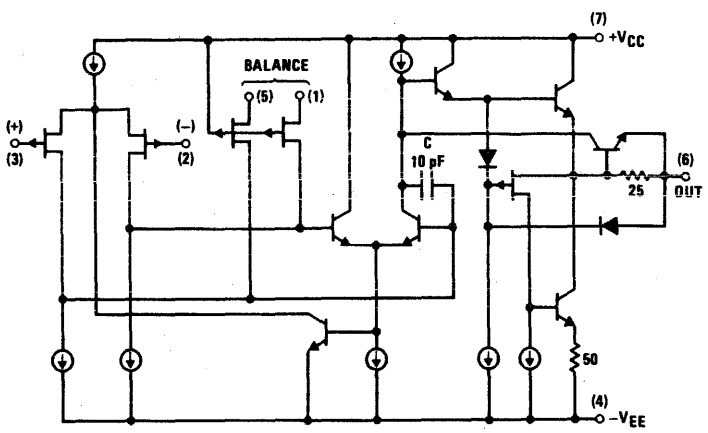
LFT155/LFT156



Low input offset voltage	0.5 mV max
Low input offset voltage temperature drift	5 μV/°C max
Low input bias current	50 pA max
Low input offset current	10 pA max
High common-mode rejection ratio	95 dB min
High input impedance	$10^{12}\Omega$
Low input noise current	0.01 pA/$\sqrt{Hz}$
Large DC voltage gain	106 dB

LFT156/LFT356

Fast slew rate	10 V/μs min
Wide gain bandwidth	4 MHz min
Extremely fast settling	1.5 μs to 0.01%
Low input noise voltage	12 nV/$\sqrt{Hz}$



Typical Application

12-Bit Accurate Buffer

Greater than 12-bit accuracy without adjustment

Notes for Electrical Characteristics

Note 1: The maximum power dissipation for these devices must be derated at elevated temperatures and is dictated by T_{jMAX}, θ_{jA}, and the ambient temperature, T_A. The maximum available power dissipation at any temperature is $P_d = (T_{jMAX} - T_A)/\theta_{jA}$ or the 25°C P_{dMAX}, whichever is less.

Note 2: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

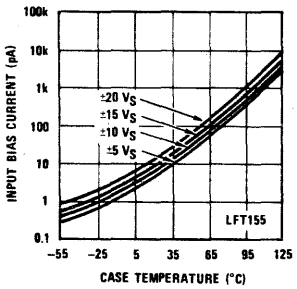
Note 3: Unless otherwise stated, these test conditions apply:

	LFT155/LFT156	LFT355/LFT356
Supply Voltage, V_S	$\pm 15V \leq V_S \leq \pm 20V$	$\pm 15V \leq V_S \leq \pm 18V$
T_A	$-55°C \leq T_A \leq +125°C$	$0°C \leq T_A \leq +70°C$
T_{HIGH}	+125°C	+70°C

and V_{OS}, I_B and I_{OS} are measured at $V_{CM} = 0$.

Note 4: The Temperature Coefficient of the adjusted input offset voltage changes only a small amount (0.5 $\mu V/°C$ typically) for each mV of adjustment from its original unadjusted value. Common-mode rejection and open loop voltage gain are also unaffected by offset adjustment.

Note 5: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_j. Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_d. $T_j = T_A + \Theta_{jA} P_d$ where Θ_{jA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.



Note 6: Supply Voltage Rejection is measured for both supply magnitudes increasing or decreasing simultaneously, in accordance with common practice.

Note 7; Settling time is defined here, for a unity gain inverter connection using 2 kΩ resistors. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within 0.01% of its final value from the time a 10V step input is applied to the inverter. See Settling Time Test Circuit.

LM140A/LM140/LM340A/LM340 Series 3-Terminal Positive Regulators

General Description

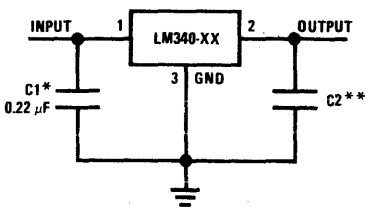
The LM140A/LM140/LM340A/LM340 series of positive 3-terminal voltage regulators are designed to provide superior performance as compared to the previously available 78XX series regulator. Computer programs were used to optimize the electrical and thermal performance of the packaged IC which results in outstanding ripple rejection, superior line and load regulation in high power applications (over 15W).

With these advances in design, the LM340 is now guaranteed to have line and load regulation that is a factor of 2 better than previously available devices. Also, all parameters are guaranteed at 1A vs 0.5A output current. The LM140A/LM340A provide tighter output voltage tolerance, ±2% along with 0.01%/V line regulation and 0.3%/A load regulation.

Current limiting is included to limit peak output current to a safe value. Safe area protection for the output transistor is provided to limit internal power dissipation. If internal power dissipation becomes too high for the heat sinking provided, the thermal shutdown circuit takes over limiting die temperature.

Considerable effort was expended to make the LM140-XX series of regulators easy to use and minimize the number of external components. It is not necessary to bypass the output, although this does improve transient response. Input bypassing is needed only if the regulator is located far from the filter capacitor of the power supply.

Although designed primarily as fixed voltage regulators, these devices can be used with external components to obtain adjustable voltages and currents.

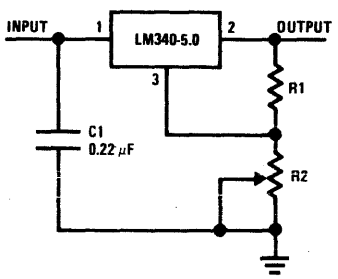


The entire LM140A/LM140/LM340A/LM340 series of regulators is available in the metal TO-3 power package and the LM340A/LM340 series is also available in the TO-220 plastic power package.

Features

- Complete specifications at 1A load
- Output voltage tolerances of ±2% at T_j = 25°C and ±4% over the temperature range (LM140A/LM340A)
- Fixed output voltages available 5, 6, 8, 10 12, 15, 18 and 24V
- Line regulation of 0.01% of V_{OUT}/V ΔV_{IN} at 1A load (LM140A/LM340A)
- Load regulation of 0.3% of V_{OUT}/A ΔI_{LOAD} (LM140A/LM340A)
- Internal thermal overload protection
- Internal short-circuit current limit
- Output transistor safe area protection

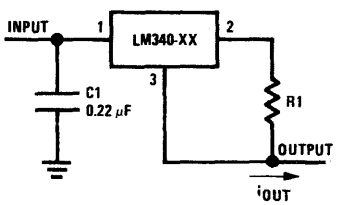
Typical Applications



Fixed Output Regulator

*Required if the regulator is located far from the power supply filter

**Although no output capacitor is needed for stability, it does help transient response. (If needed, use 0.1 μF, ceramic disc)



Adjustable Output Regulator

$V_{OUT} = 5V + (5V/R1 + I_Q)\,R2$

$5V/R1 > 3\,I_Q$, load regulation $(L_r) \approx [(R1 + R2)/R1]\,(L_r$ of LM340-5)

Current Regulator

$$I_{OUT} = \frac{V2\text{-}3}{R1} + I_Q$$

ΔI_Q = 1.3 mA over line and load changes

Note 1: Thermal resistance of the TO-3 package (K, KC) is typically 4°C/W junction to case and 35°C/W case to ambient. Thermal resistance of the TO-220 package (T) is typically 4°C/W junction to case and 60°C/W case to ambient.

Note 2: All characteristics are measured with a capacitor across the input of 0.22 μF and a capacitor across the output of 0.1 μF. All characteristics except noise voltage and ripple rejection ratio are measured using pulse techniques ($t_W \leq$ 10 ms, duty cycle ≤ 5%). Output voltage changes due to changes in internal temperature must be taken into account separately.

Electrical Characteristics LM140 (Note 2)

$-55°C \leq T_j \leq +150°C$ unless otherwise noted.

Application Hints

The LM340 is designed with thermal protection, output short-circuit protection and output transistor safe area protection. However, as with *any* IC regulator, it becomes necessary to take precautions to assure that the regulator is not inadvertently damaged. The following describes possible misapplications and methods to prevent damage to the regulator.

Shorting the Regulator Input: When using large capacitors at the output of these regulators that have V_{OUT} greater than 6V, a protection diode connected input to output *(Figure 1)* may be required if the input is shorted to ground. Without the protection diode, an input short will cause the input to rapidly approach ground potential, while the output remains near the initial V_{OUT} because of the stored charge in the large output capacitor. The capacitor will then discharge through reverse biased emitter-base junction of the pass device, Q16, which breaks down at 6.5V and forward biases the base-collector junction. If the energy released by the capacitor into the emitter-base junction is large enough, the junction and the regulator will be destroyed. The fast diode in *Figure 1* will shunt the capacitor's discharge current around the regulator.

Raising the Output Voltage above the Input Voltage: Since the output of the LM340 does not sink current, forcing the output high can cause damage to internal low current paths in a manner similar to that just described in the "Shorting the Regulator Input" section.

Regulator Floating Ground *(Figure 2)*: When the ground pin alone becomes disconnected, the output approaches the unregulated input, causing possible damage to other circuits connected to V_{OUT}. If ground is reconnected with power "ON", damage may also occur to the regulator. This fault is most likely to occur when plugging in regulators or modules with on card regulators into powered up sockets. Power should be turned off first, or ground should be connected first if power must be left on.

Transient Voltages: If transients exceed the maximum rated input voltage of the 340, or reach more than 0.8V below ground and have sufficient energy, they will damage the regulator. The solution is to use a large input capacitor, a series input breakdown diode, a choke, a transient suppressor or a combination of these.

LM150/LM250/LM350
3 Amp Adjustable Power Regulators

General Description

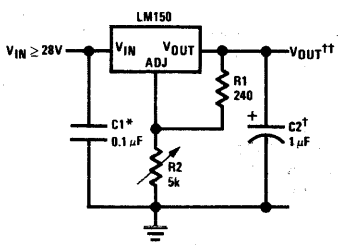
The LM150/LM250/LM350 are adjustable 3-terminal positive voltage regulators capable of supplying in excess of 3A over a 1.2V to 33V output range. They are exceptionally easy to use and require only 2 external resistors to set the output voltage. Further, both line and load regulation are comparable to discrete designs. Also, the LM150 is packaged in standard transistor packages which are easily mounted and handled.

In addition to higher performance than fixed regulators, the LM150 series offers full overload protection available only in IC's. Included on the chip are current limit, thermal overload protection and safe area protection. All overload protection circuitry remains fully functional even if the adjustment terminal is accidentally disconnected.

Normally, no capacitors are needed unless the device is situated far from the input filter capacitors in which case an input bypass is needed. An optional output capacitor can be added to improve transient response. The adjustment terminal can be bypassed to achieve very high ripple rejections ratios which are difficult to achieve with standard 3-terminal regulators.

Besides replacing fixed regulators or discrete designs, the LM150 is useful in a wide variety of other applications. Since the regulator is "floating" and sees only the input-to-output differential voltage, supplies of several hundred volts can be regulated as long as the maximum input to output differential is not exceeded.

Also, it makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM150 can be used as a precision current regulator. Supplies with electronic shutdown can be achieved by clamping the adjustment terminal to ground which programs the output to 1.2V where most loads draw little current.



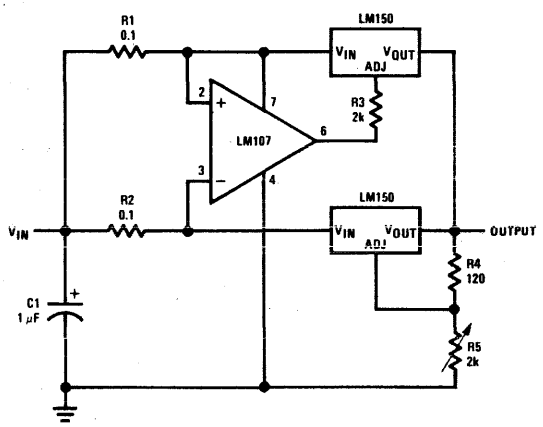
The LM150/LM250/LM350 are packaged in standard steel TO-3 transistor packages. The LM150 is rated for operation from −55°C to +150°C, the LM250 from −25°C to +150°C and the LM350 from 0°C to +125°C.

Features

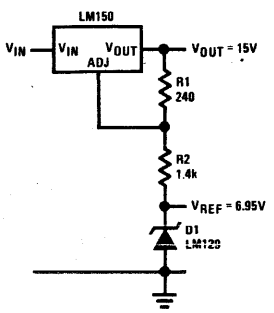
- Adjustable output down to 1.2V
- Guaranteed 3A output current
- Line regulation typically 0.005%/V
- Load regulation typically 0.1%
- Guaranteed thermal regulation
- Current limit constant with temperature
- **100% electrical burn-in in thermal limit**
- Eliminates the need to stock many voltages
- Standard 3-lead transistor package
- 86 dB ripple rejection

Typical Applications

1.2V–25V Adjustable Regulator



†Optional—improves transient response



*Needed if device is far from filter capacitors

††$V_{OUT} = 1.25V \left(1 + \frac{R2}{R1}\right)$

Application Hints

In operation, the LM150 develops a nominal 1.25V reference voltage, V_{REF}, between the output and adjustment terminal. The reference voltage is impressed across program resistor R1 and, since the voltage is constant, a constant current I_1 then flows through the output set resistor R2, giving an output voltage of

$$V_{OUT} = V_{REF}\left(1 + \frac{R2}{R1}\right) + I_{ADJ}R2.$$

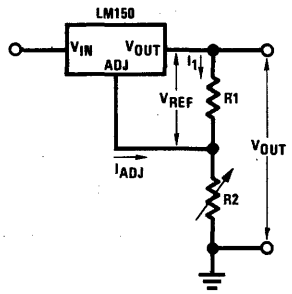

FIGURE 1

Since the 50 μA current from the adjustment terminal represents an error term, the LM150 was designed to minimize I_{ADJ} and make it very constant with line and load changes. To do this, all quiescent operating current is returned to the output establishing a minimum load current requirement. If there is insufficient load on the output, the output will rise.

External Capacitors

An input bypass capacitor is recommended. A 0.1 μF disc or 1 μF solid tantalum on the input is suitable input bypassing for almost all applications. The device is more sensitive to the absence of input bypassing when adjustment or output capacitors are used but the above values will eliminate the possibility of problems.

The adjustment terminal can be bypassed to ground on the LM150 to improve ripple rejection. This bypass capacitor prevents ripple from being amplified as the output voltage is increased. With a 10 μF bypass capacitor 86 dB ripple rejection is obtainable at any output level. Increases over 10 μF do not appreciably improve the ripple rejection at frequencies above 120 Hz. If the bypass capacitor is used, it is sometimes necessary to include protection diodes to prevent the capacitor from discharging through internal low current paths and damaging the device.

In general, the best type of capacitors to use are solid tantalum. Solid tantalum capacitors have low impedance even at high frequencies. Depending upon capacitor construction, it takes about 25 μF in aluminum electrolytic to equal 1 μF solid tantalum at high frequencies. Ceramic capacitors are also good at high frequencies, but some types have a large decrease in capacitance at frequencies around 0.5 MHz. For this reason, 0.01 μF disc may seem to work better than a 0.1 μF disc as a bypass.

Although the LM150 is stable with no output capacitors, like any feedback circuit, certain values of external capacitance can cause excessive ringing. This occurs with values between 500 pF and 5000 pF. A 1 μF solid tantalum (or 25 μF aluminum electrolytic) on the output swamps this effect and insures stability.

Load Regulation

The LM150 is capable of providing extremely good load regulation but a few precautions are needed to obtain maximum performance. The current set resistor connected between the adjustment terminal and the output terminal (usually 240Ω) should be tied directly to the output of the regulator rather than near the load. This eliminates line drops from appearing effectively in series with the reference and degrading regulation. For example, a 15V regulator with 0.05Ω resistance between the regulator and load will have a load regulation due to line resistance of 0.05Ω x I_L. If the set resistor is connected near the load the effective line resistance will be 0.05Ω (1 + R2/R1) or in this case, 11.5 times worse.

Figure 2 shows the effect of resistance between the regulator and 240Ω set resistor.

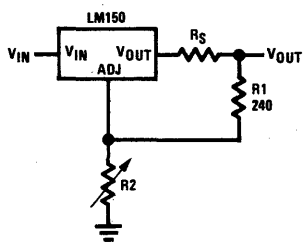

FIGURE 2. Regulator with Line Resistance in Output Lead

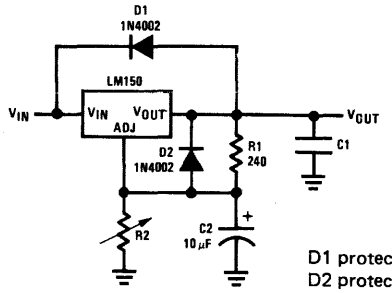
With the TO-3 package, it is easy to minimize the resistance from the case to the set resistor, by using 2 separate leads to the case. The ground of R2 can be returned near the ground of the load to provide remote ground sensing and improve load regulation.

Protection Diodes

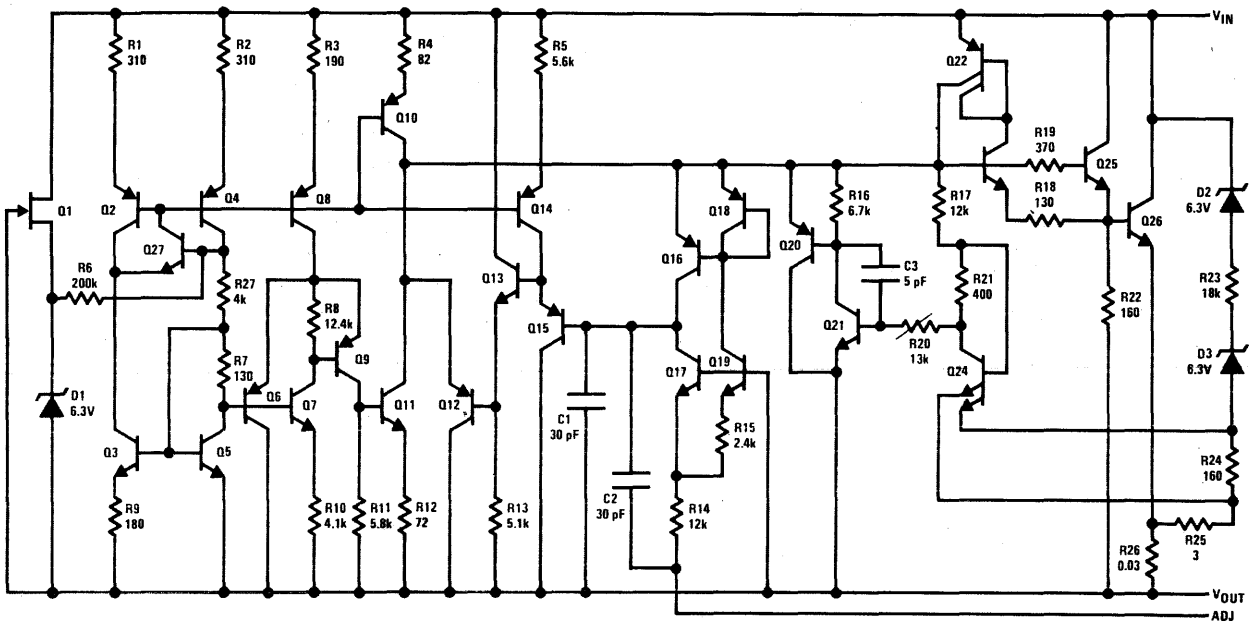


When external capacitors are used with *any* IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator. Most 10 μF capacitors have low enough internal series resistance to deliver 20A spikes when shorted. Although the surge is short, there is enough energy to damage parts of the IC.

When an output capacitor is connected to a regulator and the input is shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage of the regulator, and the rate of decrease of V_{IN}. In the LM150, this discharge path is through a large junction that is able to sustain 25A surge with no problem. This is not true of other types of positive

Application Hints (Continued)

regulators. For output capacitors of 25 μF or less, there is no need to use diodes.



The bypass capacitor on the adjustment terminal can discharge through a low current junction. Discharge occurs when *either* the input or output is shorted. Internal to the LM150 is a 50Ω resistor which limits the peak discharge current. No protection is needed for output voltages of 25V or less and 10 μF capacitance. *Figure 3* shows an LM150 with protection diodes included for use with outputs greater than 25V and high values of output capacitance.

$$V_{OUT} = 1.25V \left(1 + \frac{R2}{R1}\right) + R2I_{ADJ}$$

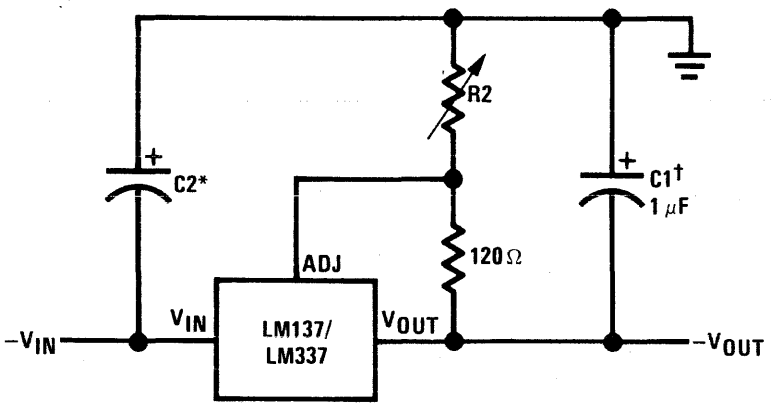
LM137/LM237/LM337 3-Terminal Adjustable Negative Regulators

General Description

The LM137/LM237/LM337 are adjustable 3-terminal negative voltage regulators capable of supplying in excess of −1.5A over an output voltage range of −1.2V to −37V. These regulators are exceptionally easy to apply, requiring only 2 external resistors to set the output voltage and 1 output capacitor for frequency compensation. The circuit design has been optimized for excellent regulation and low thermal transients. Further, the LM137 series features internal current limiting, thermal shutdown and safe-area compensation, making them virtually blowout-proof against overloads.



The LM137/LM237/LM337 serve a wide variety of applications including local on-card regulation, programmable-output voltage regulation or precision current regulation. The LM137/LM237/LM337 are ideal complements to the LM117/LM217/LM317 adjustable positive regulators.

Features

- Output voltage adjustable from −1.2V to −37V
- 1.5A output current guaranteed, −55°C to +150°C
- Line regulation typically 0.01%/V
- Load regulation typically 0.3%
- Excellent thermal regulation, 0.002%/W
- 77 dB ripple rejection
- Excellent rejection of thermal transients
- 50 ppm/°C temperature coefficient
- Temperature-independent current limit
- Internal thermal overload protection
- 100% electrical burn-in
- Standard 3-lead transistor package

Typical Applications

Adjustable Negative Voltage Regulator

$$-V_{OUT} = -1.25V\left(1 + \frac{R2}{120\Omega}\right)$$

†C1 = 1 μF solid tantalum or 10 μF aluminum electrolytic required for stability
*C2 = 1 μF solid tantalum is required only if regulator is more than 4" from power-supply filter capacitor

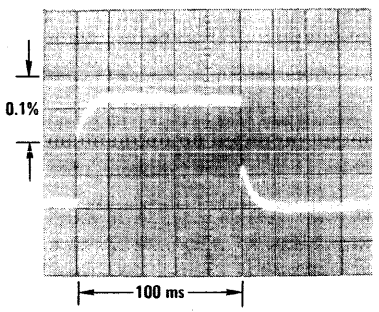
Schematic Diagram

Thermal Regulation



When power is dissipated in an IC, a temperature gradient occurs across the IC chip affecting the individual IC circuit components. With an IC regulator, this gradient can be especially severe since power dissipation is large. Thermal regulation is the effect of these temperature gradients on output voltage (in percentage output change) per Watt of power change in a specified time. Thermal regulation error is independent of electrical regulation or temperature coefficient, and occurs within 5 ms to 50 ms after a change in power dissipation. Thermal regulation depends on IC layout as well as electrical design. The thermal regulation of a voltage regulator is defined as the percentage change of V_{OUT}, per Watt, within the first 10 ms after a step of power is applied. The LM137's specification is 0.02%/W, max.

In *Figure 1*, a typical LM137's output drifts only 3 mV (or 0.03% of V_{OUT} = −10V) when a 10W pulse is applied for 10 ms. This performance is thus well inside the specification limit of 0.02%/W x 10W = 0.2% max. When the 10W pulse is ended, the thermal regulation again shows a 3 mV step as the LM137 chip cools off. Note that the load regulation error of about 8 mV (0.08%) is additional to the thermal regulation error. In *Figure 2*, when the 10W pulse is applied for 100 ms, the output drifts only slightly beyond the drift in the first 10 ms, and the thermal error stays well within 0.1% (10 mV).

LM117/LM217/LM317 3-terminal adjustable regulator

general description

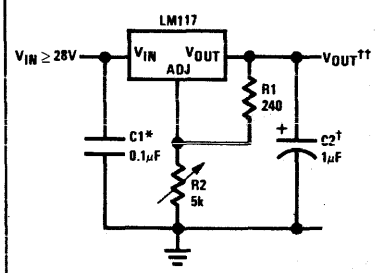
The LM117/LM217/LM317 are adjustable 3-terminal positive voltage regulators capable of supplying in excess of 1.5A over a 1.2V to 37V output range. They are exceptionally easy to use and require only two external resistors to set the output voltage. Further, both line and load regulation are better than standard fixed regulators. Also, the LM117 is packaged in standard transistor packages which are easily mounted and handled.

In addition to higher performance than fixed regulators, the LM117 series offers full overload protection available only in IC's. Included on the chip are current limit, thermal overload protection and safe area protection. All overload protection circuitry remains fully functional even if the adjustment terminal is disconnected.

features

- Adjustable output down to 1.2V
- Guaranteed 1.5A output current
- Line regulation typically 0.01%/V
- Load regulation typically 0.1%
- Current limit constant with temperature
- 100% electrical burn-in
- Eliminates the need to stock many voltages
- Standard 3-lead transistor package
- 80 dB ripple rejection

Normally, no capacitors are needed unless the device is situated far from the input filter capacitors in which case an input bypass is needed. An optional output capacitor can be added to improve transient response. The adjustment terminal can be bypassed to achieve very high ripple rejections ratios which are difficult to achieve with standard 3-terminal regulators.



Besides replacing fixed regulators, the LM117 is useful in a wide variety of other applications. Since the regulator is "floating" and sees only the input-to-output differential voltage, supplies of several hundred volts can be regulated as long as the maximum input to output differential is not exceeded.

Also, it makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM117 can be used as a precision current regulator. Supplies with electronic shutdown can be achieved by clamping the adjustment terminal to ground which programs the output to 1.2V where most loads draw little current.

The LM117K, LM217K and LM317K are packaged in standard TO-3 transistor packages while the LM117H, LM217H and LM317H are packaged in a solid Kovar base TO-5 transistor package. The LM117 is rated for operation from −55°C to +150°C, the LM217 from −25°C to +150°C and the LM317 from 0°C to +125°C. The LM317T, rated for operation over a 0°C to +125°C range is available in a TO-220 plastic package.

application hints

In operation, the LM117 develops a nominal 1.25V reference voltage, V_{REF}, between the output and adjustment terminal. The reference voltage is impressed across program resistor R1 and, since the voltage is constant, a constant current I_1 then flows through the output set resistor R2, giving an output voltage of

$$V_{OUT} = V_{REF}\left(1 + \frac{R2}{R1}\right) + I_{ADJ}R2$$

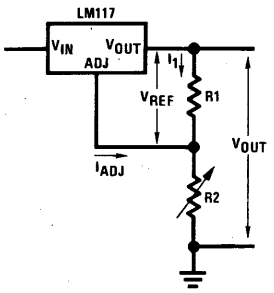

FIGURE 1.

Since the 100μA current from the adjustment terminal represents an error term, the LM117 was designed to minimize I_{ADJ} and make it very constant with line and load changes. To do this, all quiescent operating current is returned to the output establishing a minimum load current requirement. If there is insufficient load on the output, the output will rise.

External Capacitors

An input bypass capacitor is recommended. A 0.1μF disc or 1μF solid tantalum on the input is suitable input bypassing for almost all applications. The device is more sensitive to the absence of input bypassing when adjustment or output capacitors are used but the above values will eliminate the possibility of problems.

The adjustment terminal can be bypassed to ground on the LM117 to improve ripple rejection. This bypass capacitor prevents ripple from being amplified as the output voltage is increased. With a 10μF bypass capacitor 80 dB ripple rejection is obtainable at any output level. Increases over 10μF do not appreciably improve the ripple rejection at frequencies above 120 Hz. If the bypass capacitor is used, it is sometimes necessary to include protection diodes to prevent the capacitor from discharging through internal low current paths and damaging the device.

In general, the best type of capacitors to use are solid tantalum. Solid tantalum capacitors have low impedance even at high frequencies. Depending upon capacitor construction, it takes about 25μF in aluminum electrolytic to equal 1μF solid tantalum at high frequencies. Ceramic capacitors are also good at high frequencies; but some types have a large decrease in capacitance at frequencies around 0.5 MHz. For this reason, 0.01μF disc may seem to work better than a 0.1μF disc as a bypass.

Although the LM117 is stable with no output capacitors, like any feedback circuit, certain values of external capacitance can cause excessive ringing. This occurs with values between 500 pF and 5000 pF. A 1μF solid tantalum (or 25μF aluminum electrolytic) on the output swamps this effect and insures stability.

Load Regulation

The LM117 is capable of providing extremely good load regulation but a few precautions are needed to obtain maximum performance. The current set resistor connected between the adjustment terminal and the output terminal (usually 240Ω) should be tied directly to the output of the regulator rather than near the load. This eliminates line drops from appearing effectvely in series with the reference and degrading regulation. For example, a 15V regulator with 0.05Ω resistance between the regulator and load will have a load regulation due to line resistance of 0.05Ω x I_L. If the set resistor is connected near the load the effective line resistance will be 0.05Ω (1 + R2/R1) or in this case, 11.5 times worse.

Figure 2 shows the effect of resistance between the regulator and 240Ω set resistor.

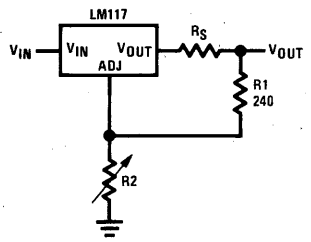

FIGURE 2. Regulator with Line Resistance in Output Lead

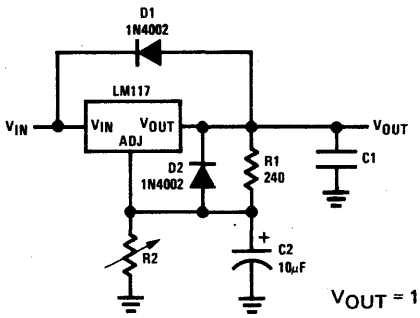
With the TO-3 package, it is easy to minimize the resistance from the case to the set resistor, by using two separate leads to the case. However, with the TO-5 package, care should be taken to minimize the wire length of the output lead. The ground of R2 can be returned near the ground of the load to provide remote ground sensing and improve load regulation.



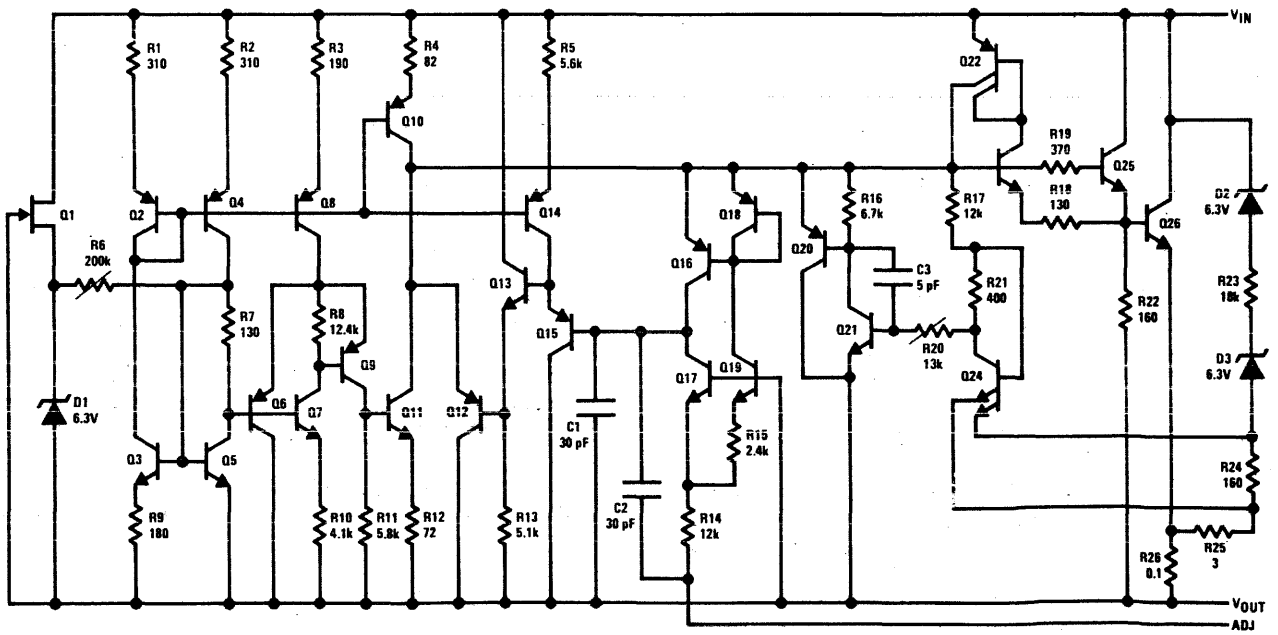
Protection Diodes

When external capacitors are used with *any* IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator. Most 10μF capacitors have low enough internal series resistance to deliver 20A spikes when shorted. Although the surge is short, there is enough energy to damage parts of the IC.

When an output capacitor is connected to a regulator and the input is shorted, the output capacitor will discharge into the output of the regulator. The discharge

current depends on the value of the capacitor, the output voltage of the regulator, and the rate of decrease of V_{IN}. In the LM117, this discharge path is through a large junction that is able to sustain 15A surge with no problem. This is not true of other types of positive regulators. For output capacitors of 25μF or less, there is no need to use diodes.

The bypass capacitor on the adjustment terminal can discharge through a low current junction. Discharge occurs when *either* the input or output is shorted. Internal to the LM117 is a 50Ω resistor which limits the peak discharge current. No protection is needed for output voltages of 25V or less and 10μF capacitance. *Figure 3* shows an LM117 with protection diodes included for use with outputs greater than 25V and high values of output capacitance.



$$V_{OUT} = 1.25V \left(1 + \frac{R2}{R1}\right) + R2 I_{ADJ}$$

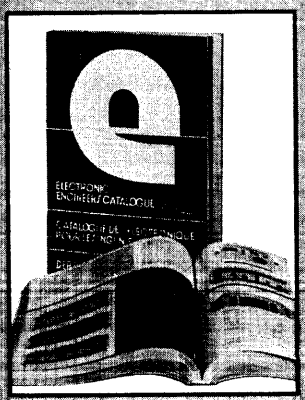
WE KNOW OUR STUFF

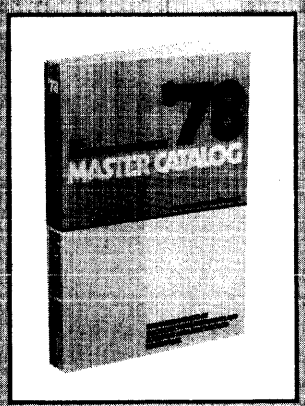


40 YEARS OF EXPERIENCE IN CATALOGING, 20 EDITIONS OF eem

eem/ELECTRONIC ENGINEERS MASTER CATALOG—

The "blue-ribbon" catalog/directory that has become "the standard of the industry" for electronic engineers, buyers and specifiers.

ELECTRONIC ENGINEERS CATALOGUE

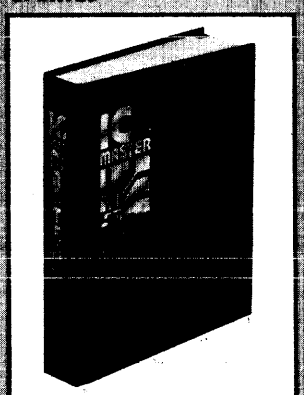


The new catalogue/directory of electronic products available to and from Western Europe and the United Kingdom. Designed especially for the European electronics engineer.

eem FILE SYSTEM—

The only filing system designed specially for the electronics engineer. Instant retrieval and organization of data sheets and catalogs.

ELECTRONIC DISTRIBUTORS MASTER CATALOG—



(Formerly O-T-S Catalog) The only national catalog designed exclusively for distributors and their customers featuring electronic parts, instruments and equipment.

ELECTRONIC PRODUCTS MAGAZINE—

The products magazine . . . A 100% product-oriented magazine including hundreds of new products and special features every month.

IC MASTER AND THE UPDATES—

The only complete single-source directory including all IC devices manufactured in the United States. Updated three times yearly with accumulative supplements.

UTP CUSTOM CATALOGS—

The Cadillac of individualized catalogs for the electronic parts distributor, featuring solely his lines and services.

UNITED COST AND PRICING SERVICES—

The electronic distributors' proven method of being up to the minute on his cost and selling prices.

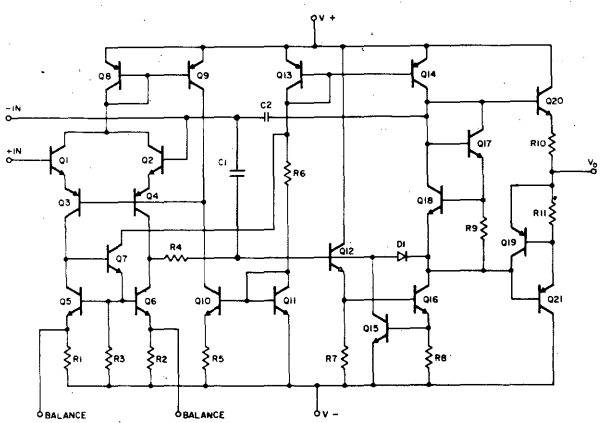
United Technical Publications, Inc., Div. of Cox Broadcasting Corp., 645 Stewart Ave., Garden City, N.Y. 11530/(516) 222-2500. TWX 510/222-1673

OP-01

INVERTING HIGH SPEED OPERATIONAL AMPLIFIER

GENERAL DESCRIPTION

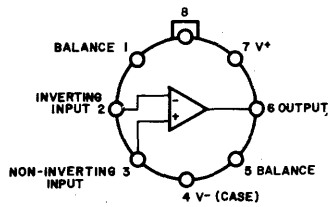
The OP-01 Series of monolithic High Speed Operational Amplifiers combines high slew rate, fast settling time output performance with excellent D.C. input characteristics.



An internal feed-forward frequency compensation network provides simplicity of application—no external capacitors are required for stable, high-speed performance. The fast output response is achieved without sacrifice in input bias current or power consumption. 250kHz power bandwidth is attained with a small signal bandwidth of 2.5 MHz, allowing non-critical board layout. The OP-01 is completely protected at both input and output, fits standard 741 sockets, and is offset nulled with a 10kΩ potentiometer.

The low offset voltage, input bias current and offset voltage drift vs. temperature provide accurate D.C. performance in applications such as channel preamplifiers, fast integrators and precision summing amplifiers. The fast output response makes the OP-01 ideal in state-variable filters, servo drivers, waveform generators, analog computing amplifiers, and D/A converter output amplifiers.

FEATURES



- Fast Settling Time . . . . . 1 μsec to 0.1%
- High Slew Rate . . . . . 18 V/μsec
- Power Bandwidth . . . . . 250 kHz
- Low Power Consumption . . . . . 90 mW Max
- Excellent D.C. Specifications
- Internally Compensated
- Ideal DAC Output Amplifier
- MIL-STD-883 Processing Available
- Fits Standard 741 Sockets
- Low Cost

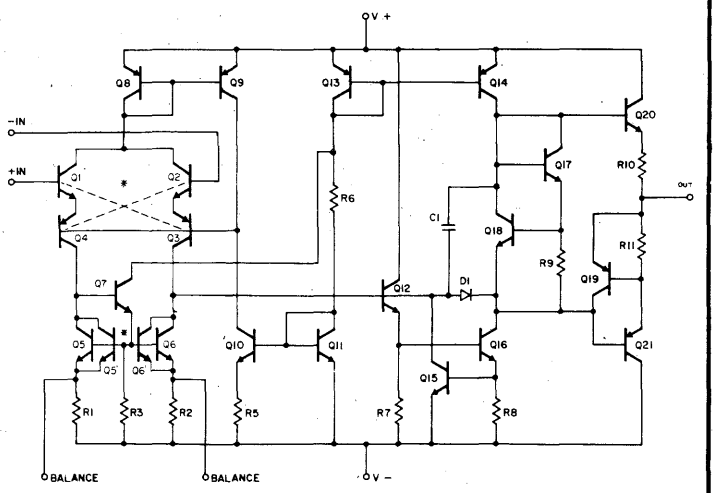
IMPROVED PM741/SSS741

OP-02

HIGH PERFORMANCE GENERAL PURPOSE OPERATIONAL AMPLIFIER



GENERAL DESCRIPTION

The OP-02 Series of High Performance General Purpose Operational Amplifiers provides significant improvements over industry-standard and "premium" 741 types while maintaining pin-for-pin compatibility, ease of application, and low cost. Key specifications, such as V_{OS}, I_{OS}, I_B, CMRR, PSRR and A_{VO}, are guaranteed over the full operating temperature range. Precision Monolithics' exclusive Silicon-Nitride "Triple Passivation" process eliminates "popcorn noise." A thermally-symmetrical input stage design provides low TCV_{OS}, TCI_{OS} and insensitivity to output load conditions. The OP-02 Series is ideal for upgrading existing designs where accuracy improvements are required and for eliminating special low drift or low noise selected types. OP-02's with MIL-STD-883 processing are available. For dual high performance matched general purpose operational amplifiers, refer to the OP-04 and OP-14 data sheets.

FEATURES

- Excellent D.C. Input Specifications
- Fits Standard 741 Socket
- Internally Compensated
- Low Noise ..... 0.65 μVp-p
- Low Drift (TCV_{OS}) ..... 8 $\mu V/^{\circ}C$
- "Premium" 741 Replacement
- 0°C/+70°C and –55°C/+125°C Models
- MIL-STD-883 Processing Available
- Silicon-Nitride Passivation
- Low Cost

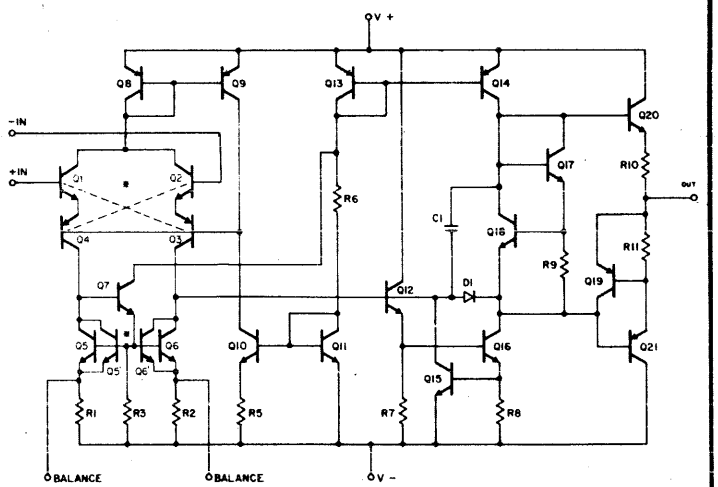
OP-04

DUAL MATCHED HIGH PERFORMANCE OPERATIONAL AMPLIFIER

GENERAL DESCRIPTION



The OP-04 Series of Dual Matched High Performance General Purpose Operational Amplifiers provides significant improvements over industry-standard 747 types while maintaining pin-for-pin compatibility, ease of application, and low cost. Key specifications, such as V_{OS}, I_{OS}, I_B, CMRR, PSRR and A_{VO}, are guaranteed over the full operating temperature range. Precision Monolithics' exclusive Silicon-Nitride "Triple Passivation" process eliminates "popcorn noise." A thermally-symmetrical input stage design provides low TCV_{OS}, TCI_{OS} and insensitivity to output load conditions. The OP-04 Series is ideal for upgrading existing designs where accuracy improvements are required and for eliminating special low drift or low noise selected types. For more stringent requirements, refer to the OP-10 Dual Matched Instrumentation Operational Amplifier data sheet.

FEATURES

- Excellent D.C. Input Specifications
- Matched V_{OS} and CMRR
- Fits Standard 747 Socket
- Internally Compensated
- Low Noise
- Low Drift
- Low Cost
- 0°C/+70°C and −55°C/+125°C Models
- Silicon-Nitride Passivation
- Models With MIL-STD-883A Class B Processing Available From Stock

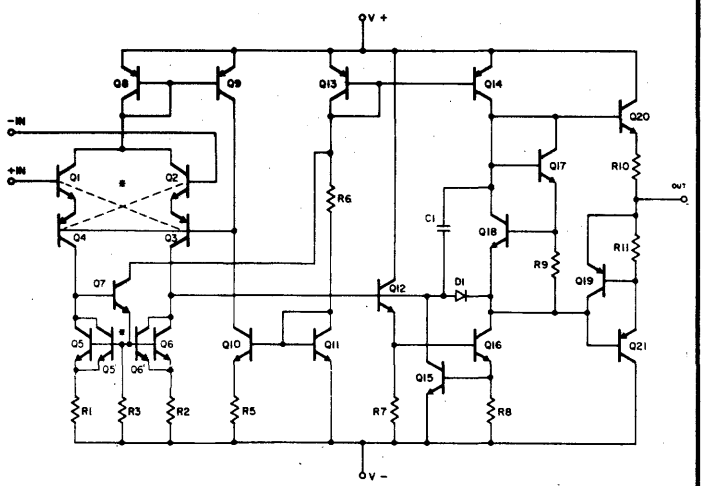
OP-14

DUAL MATCHED HIGH PERFORMANCE OPERATIONAL AMPLIFIER

GENERAL DESCRIPTION



The OP-14 Series of Dual Matched High Performance General Purpose Operational Amplifiers provides significant improvements over industry-standard 1458/1558 types while maintaining pin-for-pin compatibility, ease of application, and low cost. Key specifications, such as V_{OS}, I_{OS}, I_B, CMRR, PSRR, and A_{VO}, are guaranteed over the full operating temperature range. Precision Monolithics' exclusive Silicon-Nitride "Triple Passivation" process eliminates "popcorn noise." A thermally-symmetrical input stage design provides low TCV_{OS}, TCI_{OS} and insensitivity to output load conditions. The OP-14 Series is ideal for upgrading existing designs where accuracy improvements are required and for eliminating special low drift or low noise selected types. For similar devices with nulling capability, refer to the OP-04 data sheet.

FEATURES

- Excellent D.C. Input Specifications
- Matched V_{OS} and CMRR
- Fits Standard 1458/1558 Socket
- Internally Compensated
- Low Noise
- Low Drift
- Low Cost

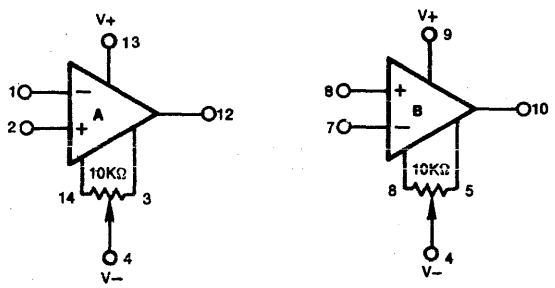
Common Mode Rejection Ratio Match	ΔCMRR	V_{CM} = ± CMVR	90	100	—	90	100	—	dB



MATCHING PARAMETER DEFINITIONS

COMMON MODE REJECTION RATIO MATCH (ΔCMRR)
The difference between the common-mode rejection ratios (expressed in volt/volt) of side A and side B.
ΔCMRR in dB = 20 $\log_{10}$ (ΔCMRR in volt/volt).

INPUT OFFSET VOLTAGE MATCH (ΔV_{os}). The difference between the offset voltages of side A and side B; ($V_{OSA} - V_{OSB}$).

OFFSET NULLING CIRCUITS

DIP (Y) PACKAGE ONLY
OP-04 ONLY

OP-04/OP-14 DEFINITIONS

INPUT OFFSET VOLTAGE (V_{os})
The voltage which must be applied between the input terminals to obtain zero output voltage with no load.

INPUT OFFSET CURRENT (i_{os})
The difference between the currents into the two input terminals when the output is at zero volts with no load.

INPUT BIAS CURRENT (I_B)
The average of the currents into the two input terminals when the output is at zero volts with no load.

INPUT VOLTAGE RANGE (CMVR)
The range of common-mode voltage on the input terminals for which the common-mode rejection specifications apply.

COMMON-MODE REJECTION RATIO (CMRR)
The ratio of the input voltage range to the peak-to-peak change in input offset voltage over this range.

POWER SUPPLY REJECTION RATIO (PSRR)
The inverse ratio of the change in input offset voltage to the change in power supply voltage producing it.

MAXIMUM OUTPUT VOLTAGE SWING (V_{om})
The peak output voltage that can be obtained without clipping.

LARGE SIGNAL VOLTAGE GAIN (A_{vo})
The ratio of the change in output voltage (over a specified range) to the change in input voltage producing it.

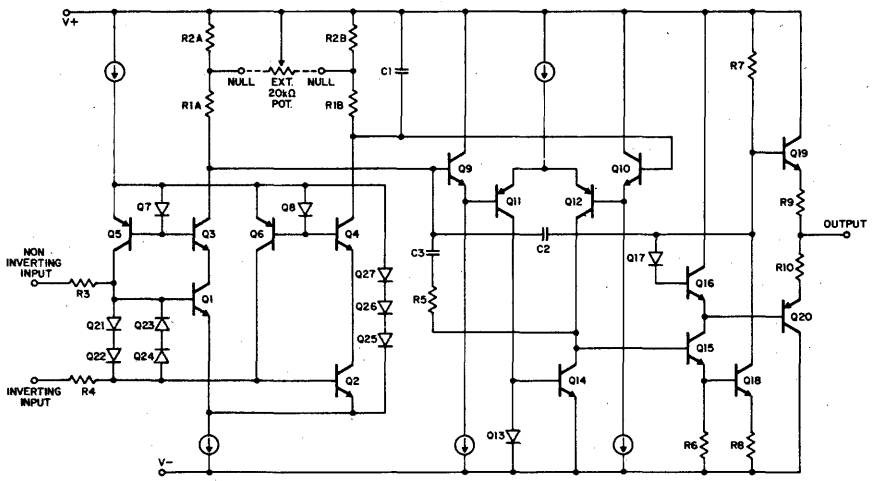
IMPROVED PM725/SSS725

OP-05

INSTRUMENTATION OPERATIONAL AMPLIFIER

GENERAL DESCRIPTION

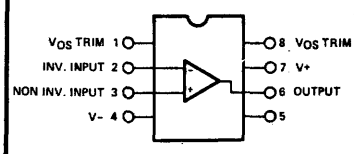
The OP-05 Series of monolithic Instrumentation Operational Amplifiers combines superlative performance in low signal level applications with the flexibility and ease of application of a fully protected, internally compensated op amp. OP-05 characteristics include low offset voltage and bias current and high gain, input impedance, CMRR and PSRR.



The OP-05 is a direct replacement in 725, 108A and unnulled 741 sockets allowing instant system performance improvement without redesign.

The OP-05 is an excellent choice for a wide variety of applications including strain gauge and thermocouple bridges, high gain active filters, buffers, integrators, and sample and hold amplifiers. For dual matched versions, refer to the OP-10 data sheet.

FEATURES



- Low Noise . . . . . 0.6μV p-p Max., 0.1 to 10Hz
- Low Drift vs. Temp . . . . . 0.5μV/°C Max
- Low Drift vs. Time . . . . . 0.3μV/Month Typ
- Low Bias Current . . . . . 2.0nA Max
- Low V_{OS} . . . . . 0.15mV Max
- High CMRR . . . . . 114dB Min
- High PSRR . . . . . 100dB Min
- High Gain . . . . . 300,000 Min
- High R_{in} Diff . . . . . 30MΩ Min
- High R_{in} CM . . . . . 200GΩ Typ
- High Slew Rate . . . . . 0.17 V/μsec Typ
- Internally Compensated . . . . . Stable to 500pF Load
- Easy to Use . . . . . Fully Protected
- Easy Offset Nulling . . . . . Single 20kΩ Pot
- Fits 725, 108A and 741 Sockets

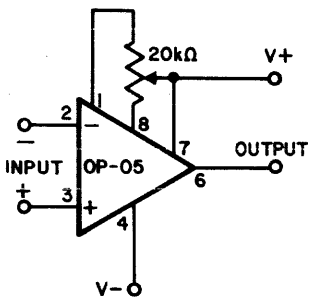
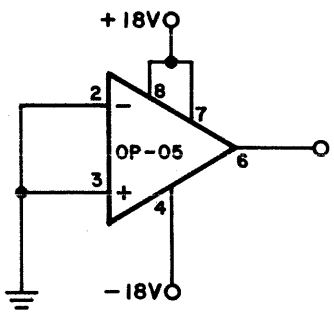
Flat Pack (L)	62°C	5.7mW/°C

Note 2: For supply voltages less than ±22V, the absolute maximum input voltage is equal to the supply voltage.



OFFSET VOLTAGE TEST CIRCUIT



LOW FREQUENCY NOISE TEST CIRCUIT

OFFSET NULLING CIRCUIT

BURN-IN CIRCUIT

APPLICATIONS INFORMATION

OP-05 Series devices may be fitted directly to 725 and 108/108A Series sockets with or without removal of external compensation components. Additionally, OP-05 may be fitted to unnulled 741 Series sockets; however, if conventional 741 nulling circuitry is in use, it should be modified or removed to enable proper OP-05 operation. The OP-05 provides stable operation with load capacitances up to 500pF and ±10V swings; larger capacitances should be decoupled with a 50Ω decoupling resistor. The designer is cautioned that stray thermoelectric voltages generated by dissimilar metals at the contacts to the input terminals can prevent realization of the drift performance indicated. Best operation will be obtained when both input contacts are maintained at the same temperature, preferably close to the temperature of the device's package.

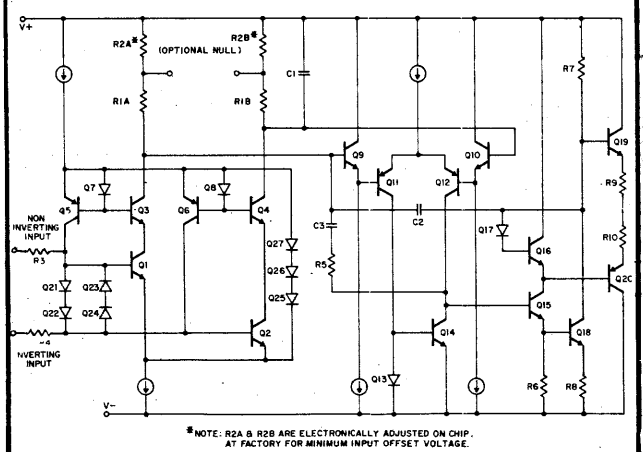
OP-07

ULTRA-LOW OFFSET VOLTAGE OP AMP

GENERAL DESCRIPTION

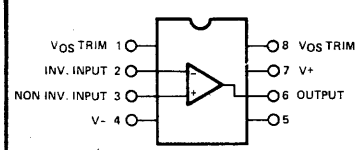
The OP-07 Series represents a breakthrough in monolithic operational amplifier performance—Vos of 10μV, TC Vos of 0.2μV/°C and long term stability of 0.2μV/month are achieved by a low noise, chopper-less bipolar input transistor amplifier circuit. Complete elimination of external components for offset nulling, frequency compensation and device protection permits extreme miniaturization and optimization of system Mean-Time-Between-Failure Rates in high performance aerospace/defense and industrial applications. Excellent device interchangeability provides reduced system assembly time and eliminates field recalibrations.



True differential inputs with wide input voltage range and outstanding common mode rejection provide maximum flexibility and performance in high noise environments and non-inverting applications. Low bias currents and extremely high input impedances are maintained over the entire temperature range.

Low cost, high volume production of OP-07 is achieved by electronic adjustment of an on-chip offset trimming network during initial factory testing. The OP-07 provides unparalleled performance for low noise, high accuracy amplification of very low level signals in transducer applications. Other applications include use in stable integrators, precision summing amplifiers for analog computation and test equipment and in ultra-precise voltage threshold detectors and comparators. The OP-07 is recommended as a replacement for modular and monolithic chopper-stabilized amplifiers where reductions in cost, noise, size and power consumption are required. Devices are available in chip form for use in hybrid circuitry. The OP-07 is a direct replacement for 725, 108A/308A, and OP-05 amplifiers; 741-types may be directly replaced by removing the 741's nulling potentiometer.

FEATURES



- Ultra-Low Vos . . . . . 10 μV
- Ultra-Low Vos Drift . . . . . 0.2 μV/°C
- Ultra-Stable vs Time . . . . . 0.2 μV/Month
- Ultra-Low Noise . . . . . 0.35 μVp-p
- No External Components Required
- Replaces Chopper amps at Lower Cost
- Single Chip Monolithic Construction
- High Common Mode Input Range . . . . . ±14.0V
- Wide Supply Voltage Range . . . . . ±3V to ±18V
- Fits 725, 108A/308A, 741,AD510 Sockets

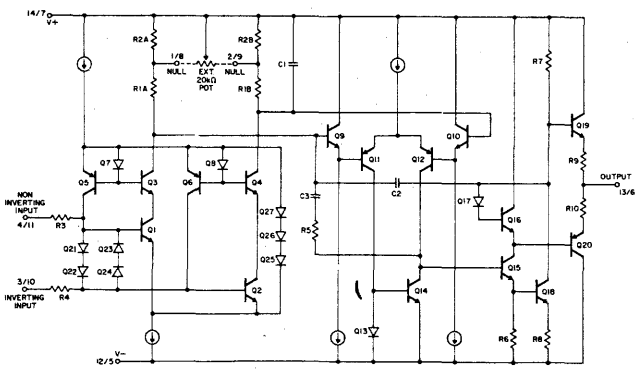
OP-10

DUAL MATCHED INSTRUMENTATION OPERATIONAL AMPLIFIER

GENERAL DESCRIPTION

The OP-10 Series of Dual Matched Instrumentation Operational Amplifiers consists of two independent monolithic high performance operational amplifiers in a single 14-pin Dual-in-Line package. For the first time, extremely tight matching of critical parameters is provided between channels of a dual operational amplifier, whereas previous dual op amp designs have made no attempt towards matching.

The excellent specifications of the individual amplifiers combined with the tight matching and temperature tracking between channels enables realization of extremely high performance instrumentation amplifier designs without resorting to laborious and expensive selection and matching of discrete amplifiers. The designer is assured of achieving the full performance guaranteed by the specification as the common package eliminates the unavoidable temperature differentials incurred by all designs utilizing separately housed amplifiers.



Matching between channels is provided on all critical parameters including offset voltage, tracking of offset voltage vs. temperature, non-inverting bias currents, and common mode and power supply rejection ratios. The individual amplifiers feature extremely low offset voltage, offset voltage drift, low noise voltage, low bias current and are completely compensated and protected.

FEATURES

- Extremely Tight Matching
- Excellent Individual Amplifier Parameters
- Tight Offset Voltage Match . . . . . 0.18mV Max
- Tight Offset Voltage Match vs. Temp. . 0.8 μV/°C Max
- Tight Common Mode Rejection Match . . 114 dB Min
- Tight Power Supply Rejection Match . . . 100 dB Min
- Tight Bias Current Match. . . . . 2.8 nA Max
- Low Noise . . . . . 0.6 μVp-p Max
- Low Bias Current . . . . . 3.0 nA Max
- High Common Mode Input Impedance . . 200GΩ Typ
- High Channel Separation . . . . . 126 dB Min
- Internally Compensated. . . . . Easy to Use
- Compact . . . . . 14 Pin Dip Package

IMPROVED PM108A

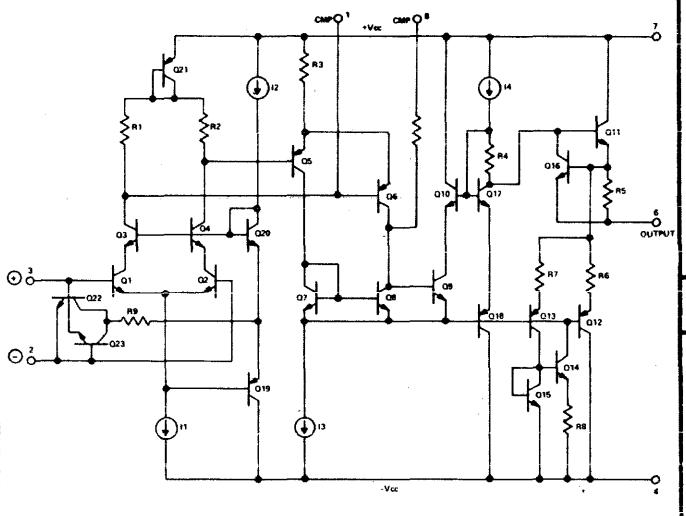
OP-08

PRECISION LOW INPUT CURRENT OP AMP

GENERAL DESCRIPTION

The PMI OP-08 is an improved version of the popular LM108A low power op amp. The OP-08 has a three times lower offset voltage and a two times lower offset voltage drift. The total worst case input offset voltage over −55°C to +125°C for the OP-08 is only 350μV, while the 108A has 900μV to 1000μV for these conditions. In addition the OP-08 drives a 2kΩ load. This is five times the output current capability of the 108A. This excellent performance is achieved by applying PMI's ion-implanted super beta process and on-chip-zener-zap trimming capabilities. For devices with identical specifications plus internal frequency compensation, see the OP-12 data sheet.

FEATURES



- Low Offset Voltage . . . . . 150μV Max.
- Low Offset Voltage Drift . . . . . 2.5μV/°C Max.
- Five Times PM108A Load Current . . . . . 5 mA Min.

Plus the Outstanding PM108A Features

- Low Offset Current . . . . . 200 pA Max.
- Low Bias Current . . . . . 2.0 nA Max.
- Low Power Consumption . . . . 18 mW max. @ ±15V
- High Common Mode Input Range . . . . ±13.5V Min.
- MIL-STD-883A Class B Processing Available
- Silicon-Nitride Passivation

OP-12

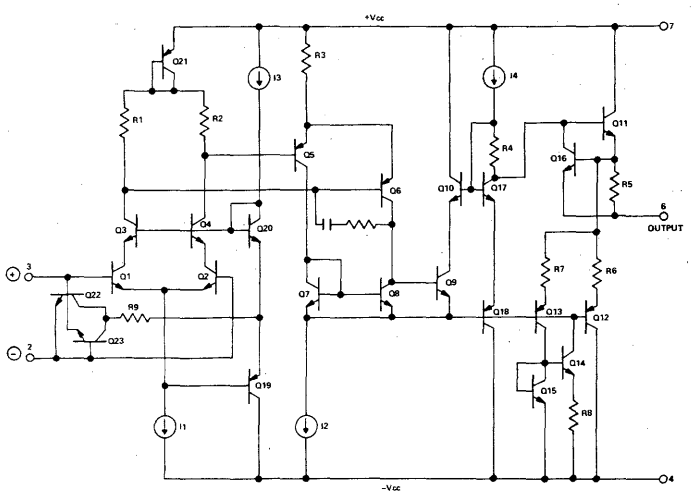
PRECISION LOW INPUT CURRENT OP AMP

INTERNALLY COMPENSATED

GENERAL DESCRIPTION

The PMI OP-12 is an improved version of the popular LM108A low power op amp. The OP-12 is internally compensated and its chip dimensions are only 42 x 58 mils. Additionally, the OP-12 has a three times lower offset voltage and a two times lower offset voltage drift. The total worst case input offset voltage over -55°C to +125°C for the OP-12 is only 350μV while the 108A has 900μV to 1000μV for these conditions. In addition the OP-12 drives a 2kΩ load. This is five times the output current capability of the 108A. This excellent performance is achieved by applying PMI's ion-implanted super beta process and on-chip zener-zap trimming capabilities. The internal compensation makes this op amp ideal for hybrid assembly applications

FEATURES



- Low Offset Voltage . . . . . 150μV Max.
- Low Offset Voltage Drift . . . . . 2.5μV/°C Max.
- Five Times PM108A Load Current . . . . . 5 mA Min.
- Internal Frequency Compensation

Plus the Outstanding PM108A Features

- Low Offset Current . . . . . 200 pA Max.
- Low Bias Current . . . . . 2.0 nA Max.
- Low Power Consumption . . . . 18 mW max. @ ±15V
- High Common Mode Input Range . . . . ±13.5V Min.
- MIL-STD-883A Class B Processing Available
- Silicon-Nitride Passivation

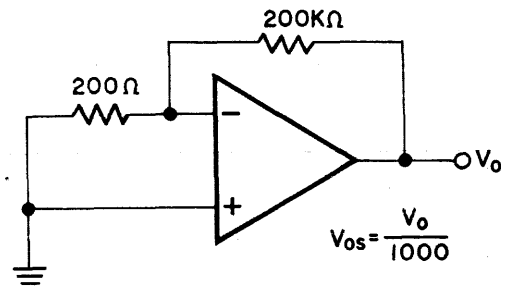
ABSOLUTE MAXIMUM RATINGS

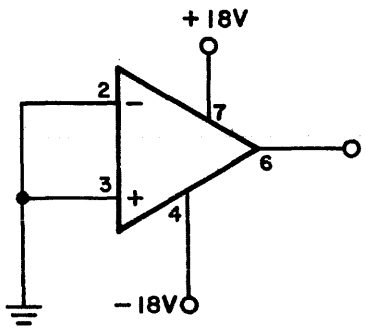
Supply Voltage	
OP-08A/12A, OP-08B/12B, OP-08C/12C	±20V
OP-08E/12E, OP-08F/12F, OP -08G/12G	±18V
Internal Power Dissipation (Note 1)	500mW
Differential Input Current (Note 2)	±10mA
Input Voltage (Note 3)	±15V
Output Short Circuit Duration	Indefinite

Operating Temperature Range	
OP-08A/12A, OP-08B/12B, OP-08C/12C	-55°C to +125°C
OP-08E/12E, OP-08F/12F, OP-08G/12G	0°C to +70°C
Storage Temperature Range	-65°C to +150°C
Lead Temperature Range	
(Soldering, 60 sec)	300°C



NOTE 1: Maximum package power dissipation vs. ambient temperature:

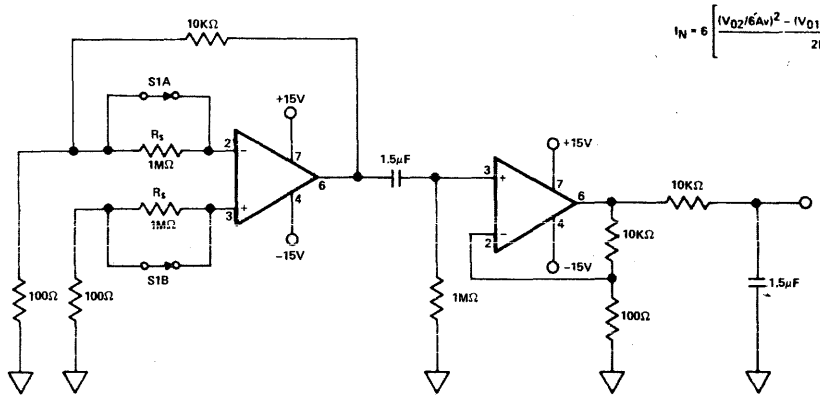
Package Type	Maximum Ambient Temperature for Rating	Derate Above Maximum Ambient Temperature
TO-99 (J)	80°C	7.1 mW/°C



NOTE 2: The inputs are shunted with back-to-back diodes for overvoltage protection. Therefore, excessive current will flow if a differential input voltage in excess of 1V is applied between the inputs unless some limiting resistance is provided.

NOTE 3: For supply voltages less than ±15V, the absolute maximum input voltage is equal to the supply voltage.

OFFSET VOLTAGE TEST CIRCUIT



BURN-IN CIRCUIT

LOW FREQUENCY NOISE TEST CIRCUIT (0.1 TO 10 Hz)

$$I_N = 6\left[\frac{(V_{02}/6A_V)^2 - (V_{01}/6A_V)^2 - 2(4kT\Delta f R_s)}{2R_s^2}\right]^{1/2}$$

NOTES: 1. S1 CLOSED MEASURES e_n (V_{01}).
2. S1 OPEN MEASURES e_n AND 1_n (V_{02}). 1_n IS COMPUTED FROM THE TWO MEASUREMENTS
3. SEE NOISE PHOTO OF e_n IN TYPICAL PERFORMANCE CURVES.

IMPROVED PM4136

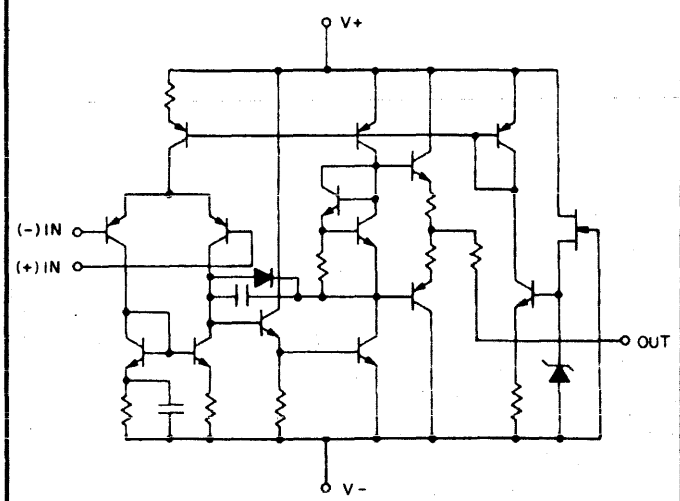
OP-09

QUAD MATCHED 741-TYPE OPERATIONAL AMPLIFIER

GENERAL DESCRIPTION

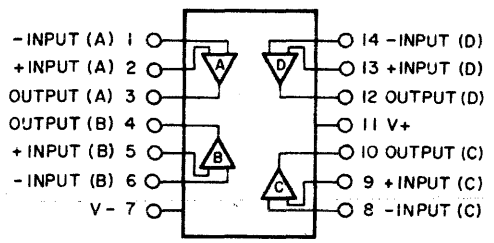
The OP-09 provides four matched 741-type operational amplifiers in a single 14-pin DIP package. The OP-09 is pin compatible with the RM4136 and RC4136 amplifiers. The amplifiers are matched for common mode rejection ratio and offset voltage. These parameters are very important in the design of instrumentation amplifiers. In addition the amplifier is designed to have equal positive-going and negative-going slew rates. This is a very important consideration for good audio system performance.

Each of the four amplifiers has the proven OP-02 advantages of low noise, low drift and excellent long term stability. Precision Monolithics' exclusive Silicon-Nitride "Triple Passivation" process eliminates "popcorn noise" and provides maximum reliability and long term stability of parameters for lowest overall system operating cost.



FEATURES

- Guaranteed V_{OS} . . . . . 500μ V MAX.
- Guaranteed Matched CMRR . . . . . 94 dB MIN.
- Guaranteed Matched V_{OS} . . . . . 750 μV MAX.
- RM4136/RC4136 Direct Replacements
- Low Noise
- Silicon-Nitride Passivation
- Internal Frequency Compensation
- Low Crossover Distortion
- Continuous Short Circuit Protection
- Low Input Bias Current



The OP-09 is ideal for use in designs requiring minimum space and cost while maintaining OP-02-type performance. OP-09's with processing per the requirements of MIL-STD-883A are available. For dual-741-type versions, see the OP-04 and OP-14 data sheets.

IMPROVED LM148

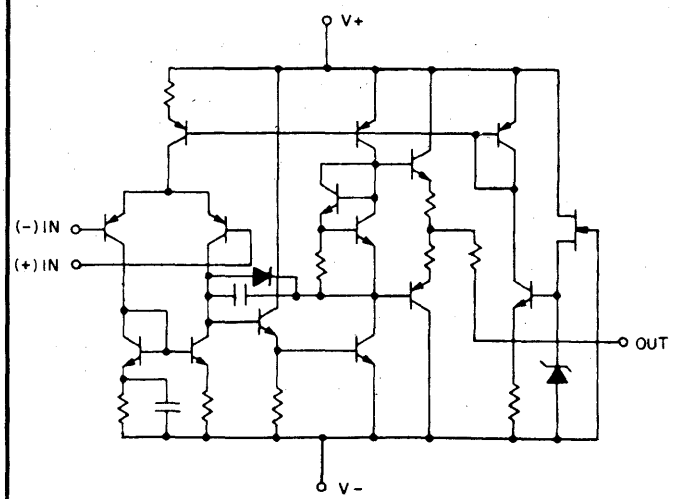
OP-11

QUAD MATCHED 741-TYPE OPERATIONAL AMPLIFIER

GENERAL DESCRIPTION

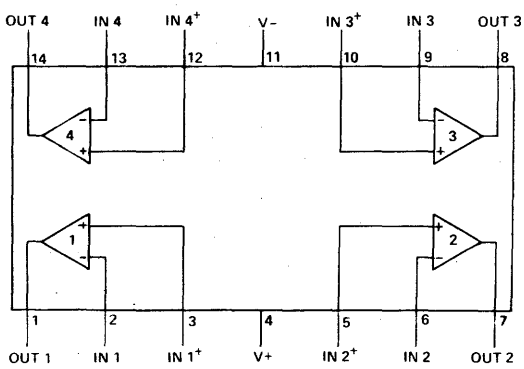
The OP-11 provides four matched 741-type operational amplifiers in a single 14-pin DIP package. The OP-11 is pin compatible with the LM148 and LM348 amplifiers. The amplifiers are matched for common mode rejection ratio and offset voltage. These parameters are very important in the design of instrumentation amplifiers. In addition the amplifier is designed to have equal positive-going and negative-going slew rates. This is a very important consideration for good audio system performance.

Each of the four amplifiers has the proven OP-02 advantages of low noise, low drift and excellent long term stability. Precision Monolithics' exclusive Silicon-Nitride "Triple Passivation" process eliminates "popcorn noise" and provides maximum reliability and long term stability of parameters for lowest overall system operating cost.



FEATURES

- Guaranteed V_{os} . . . . . 500μ V MAX.
- Guaranteed Matched CMRR . . . . . 94 dB MIN.
- Guaranteed Matched V_{os} . . . . . 750 μV MAX.
- LM148/LM348 Direct Replacements
- Low Noise
- Silicon-Nitride Passivation
- Internal Frequency Compensation
- Low Crossover Distortion
- Continuous Short Circuit Protection
- Low Input Bias Current



The OP-11 is ideal for use in designs requiring minimum space and cost while maintaining OP-02-type performance. OP-11's with processing per the requirements of MIL-STD-883A are available. For dual-741-type versions, see the OP-04 and OP-14 data sheets.

MATCHING PARAMETER DEFINITIONS

COMMON MODE REJECTION RATIO MATCH (ΔCMRR). The difference between the common-mode rejection ratios (expressed in volt/volt) of side A and side B. ΔCMRR in dB = $-20 \log_{10}$ (ΔCMRR in volt/volt). Match exists between any two amplifiers.

INPUT OFFSET VOLTAGE MATCH (ΔV_{OS}). The difference between the offset voltages of side A and side B; ($V_{OSA} - V_{OSB}$). Using amplifier A as reference then $\Delta V_{OS} = V_{OSN} - V_{OSA}$.

OP-09/OP-11 DEFINITIONS

INPUT OFFSET VOLTAGE (V_{os})
The voltage which must be applied between the input terminals to obtain zero output voltage with no load.

INPUT OFFSET CURRENT (I_{os})
The difference between the currents into the two input terminals when the output is at zero volts with no load.

INPUT BIAS CURRENT (I_B)
The average of the currents into the two input terminals when the output is at zero volts with no load.

INPUT VOLTAGE RANGE (CMVR)
The range of common-mode voltage on the input terminals for which the common-mode rejection specifications apply.

COMMON-MODE REJECTION RATIO (CMRR)
The ratio of the input voltage range to the peak-to-peak change in input offset voltage over this range.

POWER SUPPLY REJECTION RATIO (PSRR)
The inverse ratio of the change in input offset voltage to the change in power supply voltage producing it.

MAXIMUM OUTPUT VOLTAGE SWING (V_{om})
The peak output voltage that can be obtained without clipping.

LARGE SIGNAL VOLTAGE GAIN (A_{vo})
The ratio of the change in output voltage (over a specified range) to the change in input voltage producing it.

AVERAGE OFFSET VOLTAGE DRIFT (TCV_{os})
The ratio of the change in the offset voltage to the change in temperature producing it.

AVERAGE OFFSET CURRENT DRIFT (TCI_{os})
The ratio of the change in the offset current to the change in temperature producing it.

POWER DISSIPATION (P_d)
The total power dissipated in the amplifier with the output at zero volts and no load.

UNITY GAIN CLOSED LOOP BANDWIDTH (BW)
The frequency at which the magnitude of the small signal voltage gain of the amplifier, operated closed-loop as a unity-gain follower, is 3dB below unity.

INPUT NOISE VOLTAGE (e_{np-p})
The peak to peak noise voltage in a specified frequency band.

INPUT NOISE VOLTAGE DENSITY (e_n)
The rms noise voltage in a 1 Hz band surrounding a specified value of frequency.

INPUT NOISE CURRENT (i_{np-p})
The peak to peak noise current in a specified frequency band.

INPUT NOISE CURRENT DENSITY (i_n)
The rms noise current in a 1 Hz band surrounding a specified value of frequency.

IMPROVED PM155A

OP-15

PRECISION JFET INPUT OPERATIONAL AMPLIFIER

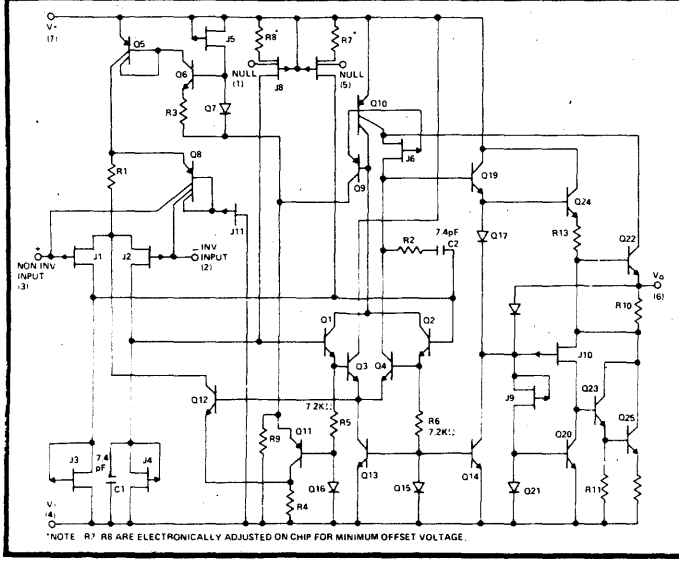
LOW SUPPLY CURRENT

GENERAL DESCRIPTION

The OP-15 provides an excellent combination of high speed and low input offset voltage. In addition the OP-15 offers the speed of the 156A op amp with 155A dissipation. To further enhance the excellent input parameters, the OP-15 uses bias current compensation to maintain low input bias current at elevated temperatures.

The OP-15 was designed to provide real precision performance along with its high speed. For example the 500μV offset voltage yields less than 1/2 LSB error in a 12 bit, 5V DAC. Although the OP-15 can be nulled, the design objective was to provide low offset voltage and drift WITHOUT NULLING. Systems become MORE COST-EFFECTIVE as the number of error correcting "knobs" decrease. PMI achieves this performance by use of an improved BI-FET process coupled with on-chip zener-zap offset trimming.

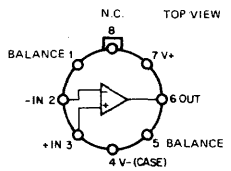
Most high speed monolithic op amps give settling time specifications to 0.01% error band, and so does PMI. Since 0.01% of 10V is 1mV, it is surprising that these same op amps have offset voltage errors in the 0.02% to 0.3% range. A large number of applications are in the 0.05% to 0.1% range, and PMI also gives specs for these error bands in its settling times. The fact that 500μV is only 0.005% of 10V is why PMI specifies settling time to a true 0.01% error band.



The combination of low input offset voltage of 500μV MAX., slew rate of 17V/μsec, and settling time of 900nsec—to 0.1%—makes the OP-15 a true precision, high speed op amp. The additional features of low supply current coupled with an input bias current of 9nA at 125°C ambient (not junction) temperature makes the OP-15 useful in a wide range of applications.

Applications include high speed amplifiers for current output DAC's, active filters, sample-and-hold buffers, and photocell amplifiers. For additional precision JFET op amps, see the OP-16 and OP-17 data sheets.

FEATURES



- High Slew Rate 17V/μs
- Fast Settling to ±0.1% . . . . . 900 nsec
- Low Input Offset Voltage . . . . . 500 μV MAX
- Low Input Offset Voltage Drift . . . . . 2.0 μV/°C
- 156 Speed with 155 Dissipation
- Wide Bandwidth . . . . . 6 MHz
- Minimum Slew Rate Guaranteed on All Models
- Temperature Compensated Input Bias Currents*
- Guaranteed Input Bias Current @ 125°C. . 9nA MAX
- Bias Current Specified WARMED UP Over Temp.
- Internal Compensation
- Low Input Noise Current . . . . . 0.01 pA $\sqrt{Hz}$
- High Common Mode Rejection Ratio 100dB
- Models With MIL-STD-883A Class B Processing Available From Stock

ABSOLUTE MAXIMUM RATINGS

Supply Voltage
- OP-15A, OP-15B, OP-15E, OP-15F: ±22V
- OP-15C, OP-15G: ±18V

Internal Power Dissipation
- All Devices: 500mW
  (The TO-99(J) package must be derated based on a thermal resistance of 150° C/W junction to ambient or 45° C/W junction to case.)

Operating Temperature Range
- OP-15A, OP-15B, OP-15C: –55°C to +125°C
- OP-15E, OP-15F, OP-15G: 0°C to +70°C

Maximum Junction Temperature (T_J)
- All Devices: +150°C

Differential Input Voltage
- OP-15A, OP-15B, OP-15E, OP-15F: ±40V
- OP-15C, OP-15G: ±30V

Input Voltage
- OP-15A, OP-15B, OP-15E, OP-15F: ±20V
- OP-15C, OP-15G: ±16V

  (Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.)

Output Short Circuit Duration: Indefinite

Storage Temperature Range: –65°C to +150°C

Lead Temperature Range (Soldering, 60 sec): +300°C

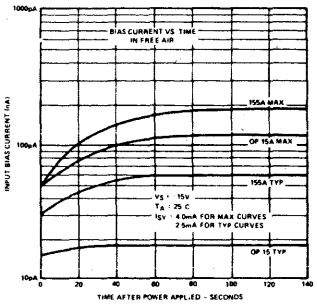
NOTE 1: Due to limited production test times the bias currents correspond to junction temperatures. The bias current vs. time (after power-on) curve clarifies this point. Since most amplifiers (in use) are on for more than 1 second, PMI also specifies the bias current for the warmed-up condition. The warmed-up bias current value is correlated to the junction temp. value via the curves of I_B vs. T_J and I_B vs. T_A. PMI has a bias current compensation circuit which gives improved bias current over the standard JFET input op amps. I_B and I_{OS} are measured at V_{CM} = 0.



NOTE 2: Settling time is defined here for a unity gain inverter connection using 2KΩ resistors. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within a specified percent of its final value from the time a 10V step input is applied to the inverter. See settling time test circuit.

NOTE 3: Parameter is not 100% tested. 90% of all units meet these specifications.

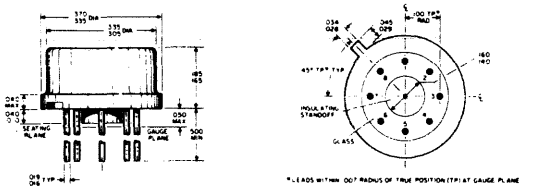
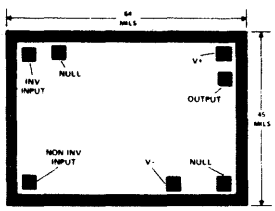
SETTLING TIME TEST CIRCUIT



APPLICATION INFORMATION

DYNAMIC OPERATING CONSIDERATIONS

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.



A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to ac ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

IMPROVED PM156A

OP-16

PRECISION JFET INPUT OPERATIONAL AMPLIFIER

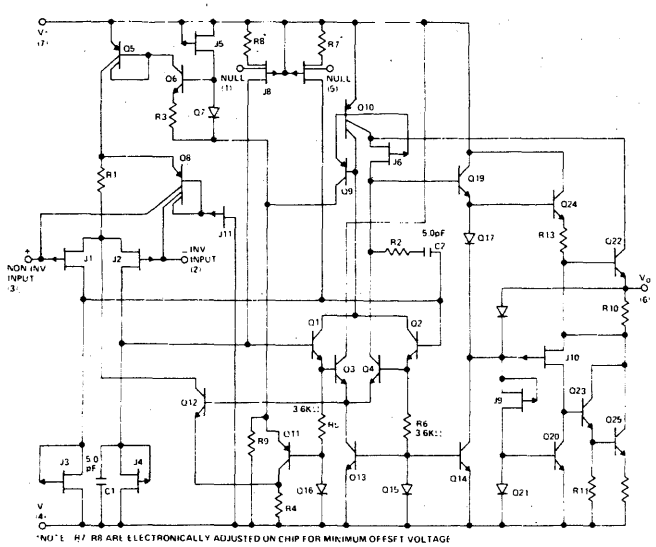
WIDE BANDWIDTH

GENERAL DESCRIPTION

The OP-16 offers a performance combination not usually found in the same op amp—high speed and low input offset voltage. Not only does the OP-16 out-perform the 156A in speed and error band, but it is clearly superior to several more costly hybrid and dielectrically-isolated op amps. In addition, the OP-16 uses bias current compensation to maintain low input bias current at elevated temperatures.

The OP-16 was designed to provide real precision performance along with its high speed. For example the 500μV offset voltage yields less than 1/2 LSB error in a 12 bit, 5V DAC. Although the OP-16 can be nulled, the design objective was to provide low offset voltage and drift WITHOUT NULLING. Systems become MORE COST-EFFECTIVE as the number of error correcting "knobs" decrease. PMI achieves this performance by use of an improved BI-FET process coupled with on-chip zener-zap offset trimming.

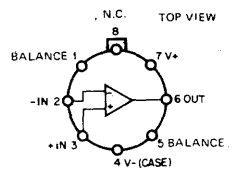
Most high speed monolithic op amps give settling time specifications to 0.01% error band, and so does PMI. Since 0.01% of 10V is 1mV, it is surprising that these same op amps have offset voltage errors in the 0.02% to 0.3% range. A large number of applications are in the 0.05% to 0.1% range, and PMI also gives specs for these error bands in its settling times. The fact that 500μV is only 0.005% of 10V is why PMI specifies settling time to a true 0.01% error band.



The combination of low input offset voltage of 500μV MAX., slew rate of 25V/μsec, and settling time of 700nsec—to 0.1%—makes the OP-16 a true precision, high speed op amp. Because of the input bias current compensation, the maximum input bias current at 125°C ambient (not junction) temperature is only 11nA. This kind of performance makes the OP-16 useful in a wide range of applications.

Applications include high speed amplifiers for current output DAC's, active filters, sample-and-hold buffers, and photocell amplifiers. For additional precision JFET op amps, see the OP-15 and OP-17 data sheets.

FEATURES



- **High Slew Rate** **25V/μs**
- **Fast Settling to ±0.1%** ..... **700 nsec**
- **Low Input Offset Voltage** ..... **500 μV MAX**
- **Low Input Offset Voltage Drift** ..... **2.0 μV/°C**
- **Wide Bandwidth** ..... **8 MHz**
- **Minimum Slew Rate Guaranteed on All Models**
- **Temperature Compensated Input Bias Currents***
- **Guaranteed Input Bias Current @ 125°C. .11nA MAX**
- **Bias Current Specified WARMED UP Over Temp.**
- **Internal Compensation**
- **Low Input Noise Current** ..... **0.01 pA $\sqrt{Hz}$**
- **High Common Mode Rejection Ratio** **100dB**
- **Models With MIL-STD-883A Class B Processing Available From Stock**

Maximum Output Voltage Swing	V_{OM}	$R_L \geq 10K\Omega$	±12	±13	–	±12	±13	–	±12	±13	–	V

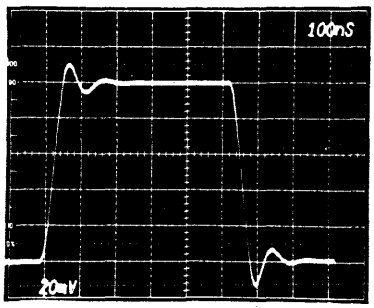
NOTE 1: Due to limited production test times the bias currents correspond to junction temperatures. The bias current vs. time (after power-on) curve clarifies this point. Since most amplifiers (in use) are on for more than 1 second, PMI also specifies the bias current for the warmed-up condition. The warmed-up bias current value is correlated to the junction temp. value via the curves of I_B vs. T_J and I_B vs. T_A. PMI has a bias current compensation circuit which gives improved bias current over the standard JFET input op amps. I_B and I_{OS} are measured at V_{CM} = 0.

NOTE 2: Settling time is defined here for a unity gain inverter connection using 2KΩ resistors. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within a specified percent of its final value from the time a 10V step input is applied to the inverter. See settling time test circuit.



NOTE 3: Parameter is not 100% tested. 90% of all units meet these specifications.

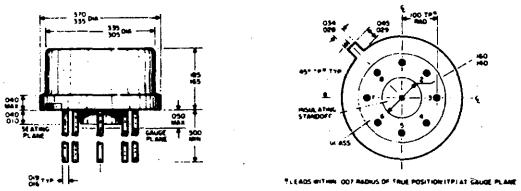
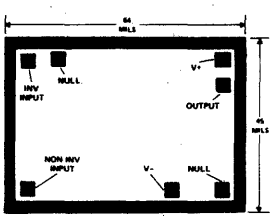
SETTLING TIME TEST CIRCUIT



APPLICATION INFORMATION

DYNAMIC OPERATING CONSIDERATIONS

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.



A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to ac ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

IMPROVED PM157A

OP-17

PRECISION JFET INPUT OPERATIONAL AMPLIFIER

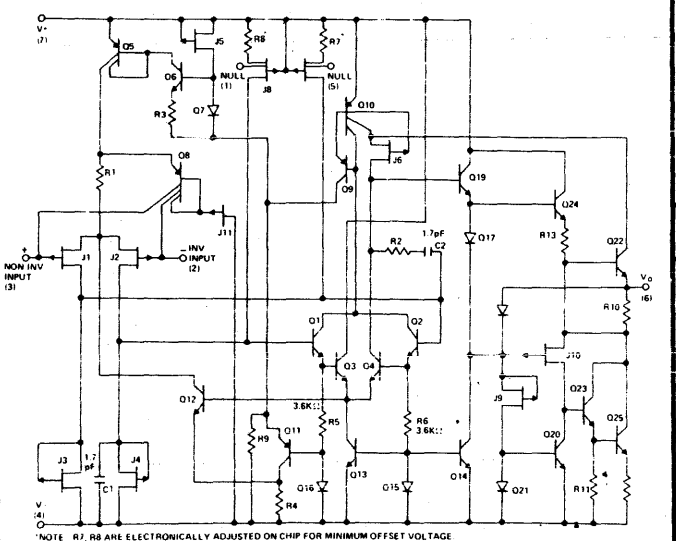
WIDE BANDWIDTH DECOMPENSATED (AV_{MIN} = 5)

GENERAL DESCRIPTION

With an unusual performance combination of 400nsec settling time and an input offset voltage of 500μV MAX., the OP-17 clearly outperforms the 157A op amp. In addition, the OP-17 is superior in both cost and performance to several dielectrically-isolated and hybrid op amps. Bias current compensation provides low input bias current at elevated temperatures.

The OP-17 was designed to provide real precision performance along with its high speed. For example the 500μV offset voltage yields less than 1/2 LSB error in a 12 bit, 5V DAC. Although the OP-17 can be nulled, the design objective was to provide low offset voltage and drift WITHOUT NULLING. Systems become MORE COST-EFFECTIVE as the number of error correcting "knobs" decrease. PMI achieves this performance by use of an improved BI-FET process coupled with on-chip zener-zap offset trimming.

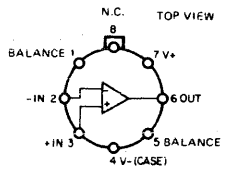
Most high speed monolithic op amps give settling time specifications to 0.01% error band, and so does PMI. Since 0.01% of 10V is 1mV, it is surprising that these same op amps have offset voltage errors in the 0.02% to 0.3% range. A large number of applications are in the 0.05% to 0.1% range, and PMI also gives specs for these error bands in its settling times. The fact that 500μV is only 0.005% of 10V is why PMI specifies settling time to a true 0.01% error band.



The combination of low input offset voltage of 500μV MAX., slew rate of 70V/μsec, and settling time of 400nsec—to 0.1%—makes the OP-17 a true precision, high speed op amp. Because of the input bias current compensation, the maximum input bias current at 125°C ambient (not junction) temperature is only 11nA. This kind of performance makes the OP-17 useful in a wide range of applications.

Applications include high speed amplifiers for current output DAC's, active filters, and photocell amplifiers. For unity gain fast follower applications see the OP-15 and OP-16 precision JFET op amp data sheets.

FEATURES



- High Slew Rate 70V/μs
- Fast Settling to ±0.1% . . . . . 400 nsec
- Low Input Offset Voltage . . . . . 500 μV MAX
- Low Input Offset Voltage Drift . . . . . 2.0 μV/°C
- Big Gain Bandwidth Product . . . . . 30 MHz
- Minimum Slew Rate Guaranteed on All Models
- Temperature Compensated Input Bias Currents*
- Guaranteed Input Bias Current @ 125°C. .11nA MAX
- Bias Current Specified WARMED UP Over Temp.
- Internal Compensation
- Low Input Noise Current . . . . . 0.01 pA $\sqrt{Hz}$
- High Common Mode Rejection Ratio 100dB
- Models with MIL-STD-883A Class B Processing Available From Stock

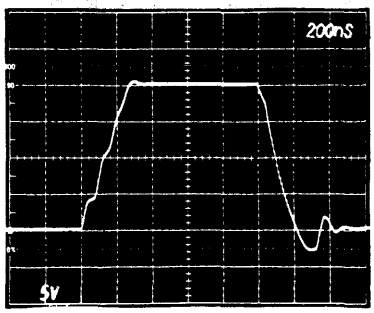
NOTE 1: Due to limited production test times the bias currents correspond to junction temperatures. The bias current vs. time (after power-on) curve clarifies this point. Since most amplifiers (in use) are on for more than 1 second, PMI also specifies the bias current for the warmed-up condition. The warmed-up bias current value is correlated to the junction temp. value via the curves of I_B vs. T_J and I_B vs. T_A. PMI has a bias current compensation circuit which gives improved bias current over the standard JFET input op amps. I_B and I_{OS} are measured at V_{CM} = 0.



NOTE 2: Settling time is defined here for a gain of five inverter connection using 2KΩ and 400Ω resistors. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within a specified percent of its final value from the time a 2V step input is applied to the inverter. See settling time test circuit.

NOTE 3: Parameter is not 100% tested. 90% of all units meet these specifications.

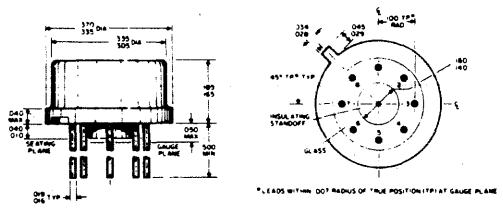
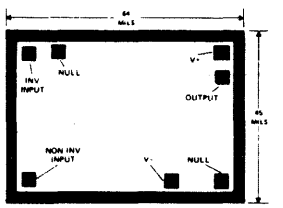
SETTLING TIME TEST CIRCUIT



APPLICATION INFORMATION

DYNAMIC OPERATING CONSIDERATIONS

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.



A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to ac ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

MAT-01

ULTRA-MATCHED MONOLITHIC DUAL TRANSISTOR

EXCELLENT LOG CONFORMANCE

GENERAL DESCRIPTION

The MAT-01 series are monolithic ultra-tightly matched dual NPN transistors, fabricated using an exclusive Silicon Nitride "Triple-Passivation" process which provides extreme stability of critical parameters versus both temperature and time. Outstanding matching characteristics include offset voltages of 40μV, temperature drift of V_{OS} of 0.15μV/°C and h_{FE} matching of 0.7%. Very high h_{FE} is provided over a six decade range of collector current, including an exceptional h_{FE} of 590 @ I_C = 10**nano** amperes! Excellent logarithmic conformance over a seven decade collector current span suggests application in log/antilog and multiplier/divider circuitry. The very low values of noise voltage and current make the MAT-01 ideal for usage in critical low-level input stages while the 6 pin TO-99 package allows direct replacement of most previous dual transistors for immediate performance improvements. The very high h_{FE} at low collector currents also makes the MAT-01 attractive in all high impedance and micropower circuit designs.

FEATURES

- **Tight V_{OS} (V_{BE} Match) . . . . 40μV Typ, 100μV Max**
- **Low TC V_{OS} . . . . . 0.15μV/°C Typ, 0.5μV/°C Max**
- **Tight h_{FE} Match . . . . . 0.7% Typ, 3.0% Max**
- **High h_{FE} . . . . . 770 Typ, 500 Min**
- **Excellent h_{FE} Linearity from 10nA to 10mA**
- **High h_{FE} at Low I_C . . . . . 590 Typ @ I_C = 10nA**
- **Low Noise Voltage . . . . 0.23μVp-p — 0.1Hz to 10Hz**
- **Excellent Long Term Stability . . 0.2μV/Month, Typ**
- **High Breakdowns . . . . . 45V and 60V Min**
- **Precision Logarithmic Conformance**
- **Direct Replacement for Most Dual Transistors**

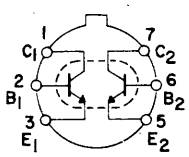
Lead Temperature (Soldering, 60 sec.)	300°C	

NOTES



Note 1: Application of reverse bias voltages in excess of rating shown can result in degradation of h_{FE} and h_{FE} matching characteristics. Do not attempt to measure BV_{EBO} greater than the 5V rating shown.

Note 2: Rating applies to applications using heat sinking to control case temperature. Derate linearly at 16.4mW/°C for case temperatures above 40°C.

Note 3: Rating applies to applications not using heat sinking; device in free air only. Derate linearly at 6.3mW/°C for ambient temperatures above 70°C.

Current Gain	h_{FE}		105	350	–	77	300	–	
Collector-Base Leakage Current	I_{CBO}	T_A = 125°C, V_{CB} = 45V, I_E = 0 (Note 4)	–	15	80	–	25	200	nA
Collector-Emitter Leakage Current	I_{CES}	T_A = 125°C, V_{CE} = 45V, V_{BE} = 0 (Note 4)	–	50	300	–	90	400	nA
Collector-Collector Leakage Current	I_{CC}	T_A = 125°C, V_{CC} = 45V	–	30	200	–	50	400	nA

NOTES:

Note 1: Exclude first hour of operation to allow for stabilization of external circuitry.

Note 2: Parameter describes long term average drift trend after first month of operation.

Note 3: Parameter is not 100% tested; 90% of all units meet this specification.

Note 4: The collector-base (I_{CBO}) and collector-emitter (I_{CEO}) leakage currents may be reduced by a factor of two to ten times by connecting the substrate (package) to a potential which is lower than either collector voltage.

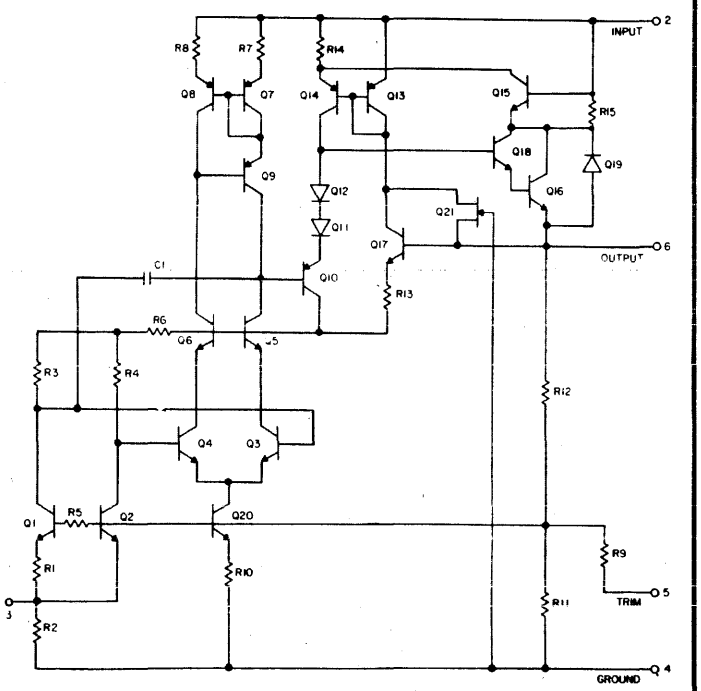
3. All of the above are physically interchangeable pin-for-pin with MAT-01 series.

REF-01

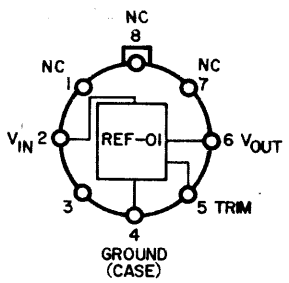
+10V PRECISION VOLTAGE REFERENCE



GENERAL DESCRIPTION

The REF-01 Precision Voltage Reference provides a stable +10V output which can be adjusted over a ±3% range with minimal effect on temperature stability. Single supply operation over an input voltage range of 12 to 40V, low current drain of 1mA, and excellent temperature stability are achieved with an improved bandgap design. Low cost, low noise and low power make the REF-01 an excellent choice whenever a stable voltage reference is required, such as in D/A and A/D converters, in portable instruments, and in digital voltmeters. Full military temperature range devices with screening to MIL-STD-883A are available.

FEATURES



- **Adjustable 10 Volt Output** . . . . . ±3%
- **Excellent Temperature Stability** . . . . . 3 ppm/°C
- **Low Noise** 20μVp-p
- **Low Power** 15mW
- **Wide Input Voltage Range** . . . . . 12 to 40V
- **High Load Driving Capability** 20mA
- **No External Components**
- **Short Circuit Proof**
- **MIL-STD-883A Screening Available**

Change in V_O Temperature Coefficient with Output Adjustment		R_p = 10kΩ	–	0.7	–	–	0.7	–	ppm/%
Line Regulation (V_{IN} = 13 to 33V) (Note 4)		0°≤T_A≤+70°C	–	0.007	0.012	–	0.007	0.012	%/V
		−55°≤T_A≤+125°C	–	0.009	0.015	–	0.009	0.015	%/V
Load Regulation (I_L = 0 to 8mA) (Note 4)		0°≤T_A≤+70°C	–	0.006	0.010	–	0.007	0.012	%/mA
		−55°≤T_A≤+125°C	–	0.007	0.012	–	0.009	0.015	%/mA

NOTE 1: ΔV_{OT} is defined as the absolute difference between the maximum output voltage and minimum output voltage over the specified temperature range expressed as a percentage of 10V:

$$\Delta V_{OT} = \frac{V_{MAX} - V_{MIN}}{10V} \times 100$$

NOTE 2: ΔV_{OT} specification applies trimmed to 10.000V or untrimmed.

NOTE 3: TCV_O is defined as ΔV_{OT} divided by the temperature range; i.e., $TCV_O(0°\text{to}+70°C) = \frac{\Delta V_{OT}\ 0°\text{to}+70°C}{70°C}$

and $TCV_O(-55°\text{to}+125°C) = \frac{\Delta V_{OT}\ -55\ \text{to}+125°C}{180°C}$

NOTE 4: Line and Load Regulation specifications include the effects of self heating.

NOTE 5: Parameter is not 100% tested; 90% of units meet this specification.

©IC MASTER 1978

REF-01 DEFINITIONS

LINE REGULATION
The ratio of the change in output voltage to the change in line voltage producing it.

LOAD REGULATION
The ratio of the change in output voltage to the change in load current producing it.

QUIESCENT CURRENT (I_{SY})
The current required from the supply to operate the device with no load.

OUTPUT TURN-ON SETTLING TIME (t_{on})
The time required for the output voltage to reach its final value within a specified error band after application of V_{IN}.

OUTPUT VOLTAGE NOISE (e_{np-p})
The peak to peak output noise voltage in a specified frequency band.

OUTPUT CHANGE WITH TEMPERATURE (ΔV_{OT})
The absolute difference between the maximum output voltage and the minimum output voltage over the specified temperature range expressed as a percentage of 10V:

$$\Delta V_{OT} = \frac{V_{MAX} - V_{MIN}}{10V} \times 100$$

OUTPUT TEMPERATURE COEFFICIENT (TCV_O)
The ratio of the output change with temperature to the specified temperature range expressed in ppm/°C.

©IC MASTER 1978

OUTPUT ADJUSTMENT

The REF-01 trim terminal can be used to adjust the output voltage over a 10V ±300mV range. This feature allows the system designer to trim system errors by setting the reference to a voltage other than 10V. Of course, the output can also be set to exactly 10.000V, or to 10.240V for binary applications.

Adjustment of the output does not significantly affect the temperature performance of the device. Typically the temperature coefficient change is 0.7 ppm/°C for 100mV of output adjustment.

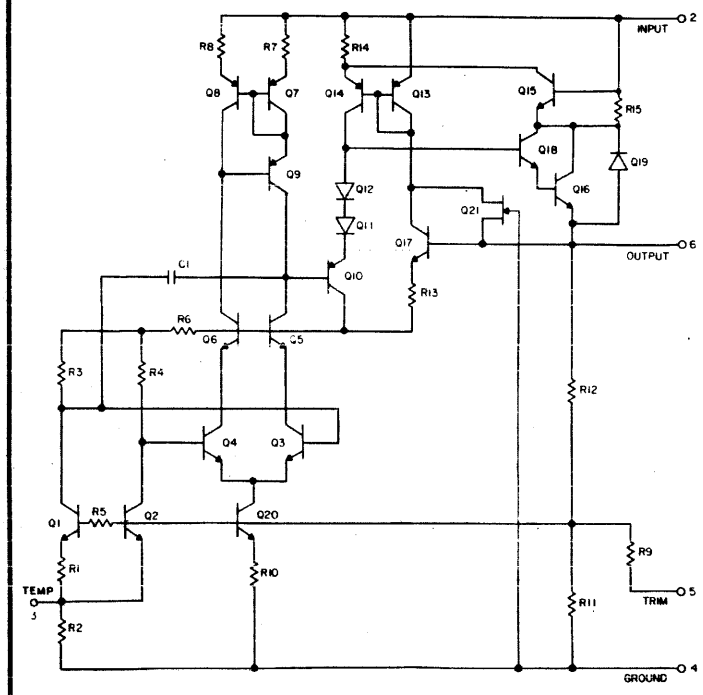
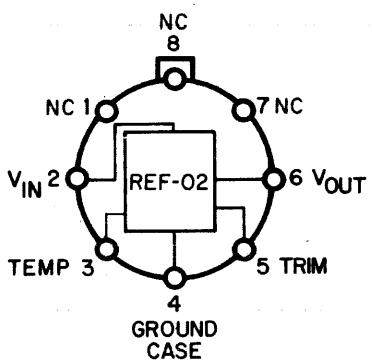
REF-02

+5V PRECISION VOLTAGE REFERENCE/THERMOMETER



GENERAL DESCRIPTION

The REF-02 Precision Voltage Reference provides a stable +5V output which can be adjusted over a ±6% range with minimal effect on temperature stability. Single supply operation over an input voltage range of 7V to 40V, low current drain of 1mA, and excellent temperature stability are achieved with an improved bandgap design. Low cost, low noise and low power make the REF-02 an excellent choice whenever a stable voltage reference is required, such as in D/A and A/D converters, in portable instruments, and in digital voltmeters. The versatility of the REF-02 is illustrated by its use as a monolithic thermometer. (See AN-18, "Thermometer Applications of the REF-02.") For +10V Precision Voltage References see the REF-01 data sheet.



FEATURES

- Temperature Voltage Output . . . . . 2.1 mV/°C
- Adjustable 5 Volt Output . . . . . ±6%
- Excellent Temperature Stability . . . . . 3 ppm/°C
- Low Noise 10μVp-p
- Low Power 15mW
- Wide Input Voltage Range . . . . . 7V to 40V
- High Load Driving Capability 20mA
- No External Components
- Short Circuit Proof
- MIL-STD-883A Screening Available

		−55° ≤ T_A ≤ +125°C	–	0.007	0.012	–	0.009	0.015	%/mA
Temp Voltage Output Temperature Coefficient	TCV_T	(Note 3)	–	2.1	–	–	2.1	–	mV/°C

NOTE 1: Parameter is not 100% tested; 90% of units meet this specification.

NOTE 2: Line and Load Regulation specifications include the effects of self heating.

NOTE 3: Limit current in or out of pin 3 to 50nA and capacitance on pin 3 to 30pF.

NOTE 4: ΔV_{OT} is defined as the absolute difference between the maximum output voltage and minimum output voltage over the specified temperature range expressed as a percentage of 5V:

$$\Delta V_{OT} = \frac{V_{MAX} - V_{MIN}}{5V} \times 100$$

NOTE 5: ΔV_{OT} specification applies trimmed to 5.000V or untrimmed.

NOTE 6: TCV_O is defined as ΔV_{OT} divided by the temperature range; i.e., TCV_O (0° to +70°C) = $\frac{\Delta V_{OT}\ 0° \text{ to } +70°C}{70°C}$

and TCV_O (−55° to +125°C) = $\frac{\Delta V_{OT}\ -55° \text{ to } +125°C}{180°C}$

©IC MASTER 1978

REF-02 DEFINITIONS

LINE REGULATION
The ratio of the change in output voltage to the change in line voltage producing it.

LOAD REGULATION
The ratio of the change in output voltage to the change in load current producing it.

QUIESCENT CURRENT (I_{SY})
The current required from the supply to operate the device with no load.

OUTPUT TURN-ON SETTLING TIME (t_{on})
The time required for the output voltage to reach its final value within a specified error band after application of V_{IN}

OUTPUT VOLTAGE NOISE (e_{np-p})
The peak to peak output noise voltage in a specified frequency band.

OUTPUT CHANGE WITH TEMPERATURE (ΔV_{OT})
The absolute difference between the maximum output voltage and the minimum output voltage over the specified temperature range expressed as a percentage of 5V:

$$\Delta V_{OT} = \frac{V_{MAX}-V_{MIN}}{5V} \times 100$$

OUTPUT TEMPERATURE COEFFICIENT (TCV_O)
The ratio of the output change with temperature to the specified temperature range expressed in ppm/°C.

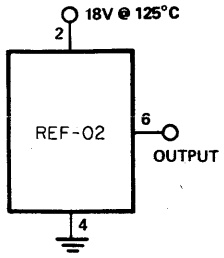
NOTE 6: TCV_O is defined as ΔV_{OT} divided by the temperature range; i.e., $TCV_O = \frac{\Delta V_{OT}}{70°C}$

©IC MASTER 1978



OUTPUT ADJUSTMENT

The REF-02 trim terminal can be used to adjust the output voltage over a 5V ±300mV range. This feature allows the system designer to trim system errors by setting the reference to a voltage other than 5V. Of course, the output can also be set to exactly 5.000V, or to 5.12V for binary applications.

Adjustment of the output does not significantly affect the temperature performance of the device. Typically the temperature coefficient change is 0.7 ppm/°C for 100mV of output adjustment.

PRELIMINARY

SMP-81

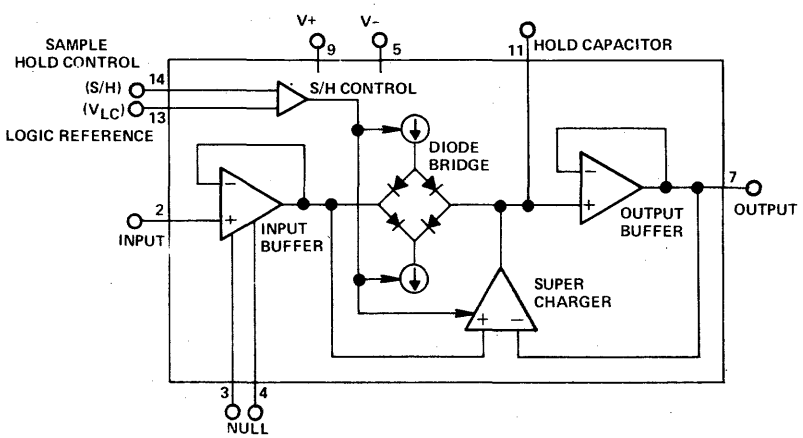
TELECOMMUNICATIONS SAMPLE AND HOLD AMPLIFIER

GENERAL DESCRIPTION

The SMP-81 precision sample and hold amplifier provides the high accuracy, low droop rate and fast acquisition ideally required for PCM telecommunication applications. The SMP-81 is a non-inverting unity gain circuit consisting of two buffer amplifiers of very high input impedance connected by a diode bridge switch.

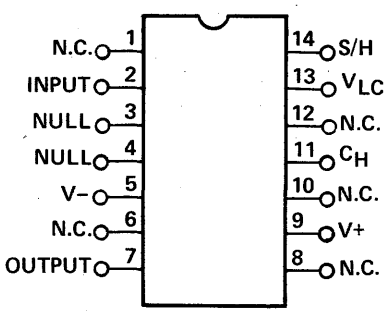
High Accuracy and Low Droop Rate

The high input impedance and low droop rate of the SMP-81 is achieved by PMI ion implant super beta process. The high input impedance permits high impedance sources applications without degrading accuracy, and low droop rate. Other features of the SMP-81 include a 0.01% accuracy, 0.3mV of combined offset voltage and step transfer error, and very low feed-through. A diode bridge switch design allows minimum charge transfer step. On-chip PMI Zener-Zap trimming, around zero, eliminates nulling for most applications.



Fast Acquisition

A unique super charger or transconductance amplifier provides up to 50mA charging current to the hold capacitor. As a result, smooth charging of the hold capacitor is achieved with minimum noise. The super charger, in conjunction with the high slewing rate input and output buffer amplifiers, permits fast acquisition operation. The adjustable logic input threshold makes the SMP-81 compatible to all logic families.



FEATURES

- Internally trimmed for a minimum offset voltage and charge transfer step 0.3mV
- Low Droop Rate Over Temperature. . . . 0.5μV/μsec
- Low Aperture Time 50ns
- Fast Acquisition Time 10V Step to 0.1% 3.5μs
- High Slew Rate 10V/μs
- High Sample Current/Hold Current Ratio . . . . . 1.7×10^8
- DTL, TTL & CMOS Compatible Logic Input
- HA-2425, DATEL SHM-IC-1, and AD-583 Socket Compatible
- Low Dissipation
- Low Cost

DEFINITIONS OF TERMS

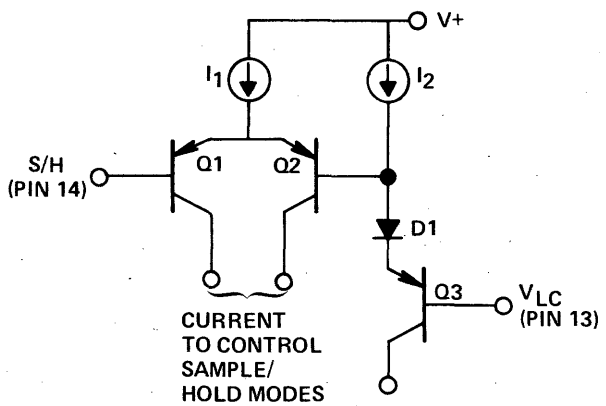
Zero Scale Error: The magnitude of the output voltage when switched to the hold mode with zero input voltage. This error consists of the sum of the offset voltage and charge transfer step voltage, and is adjustable to zero.

Acquisition Time: The minimum time required for the output to follow the input signal, within a specified percent error, after the sample command.

Voltage Gain: The ratio of the output voltage signal to the input voltage signal, in the sample mode.

HOLD CAPACITOR RECOMMENDATIONS

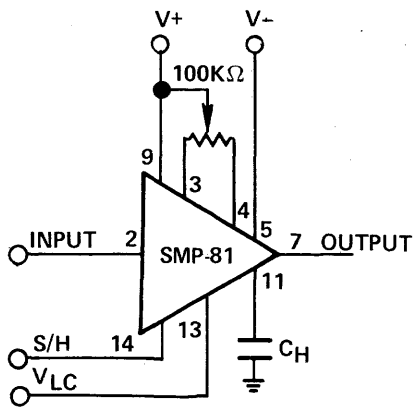
The hold capacitor (C_H) acts as a memory element and also as a compensating capacitor for the sample and hold amplifier. For stable operation, a minimum value of 0.002μF is recommended, with no limit set for the maximum value. The SMP-81 is internally trimmed for a C_H = 0.005μF. Other values of C_H will cause a zero scale shift, which can be calculated from the following equation:



$$\Delta V_{ZS} = \frac{5pC}{C_H} - 1mV$$

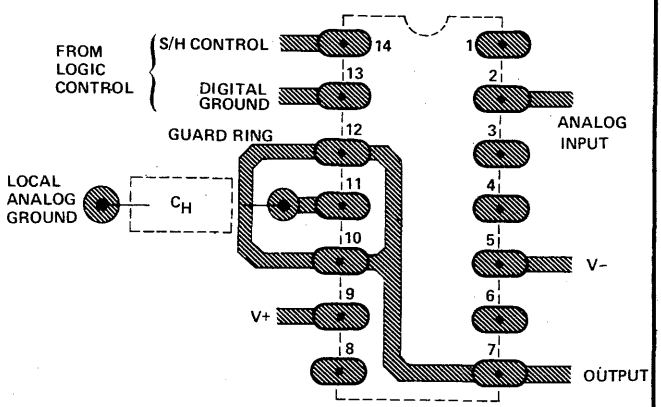
The hold capacitor should have very high insulation resistance and low dielectric absorption. For temperatures below 85°C, polystyrene capacitors are recommended, while teflon capacitors are recommended for higher temperature applications.

SMP-81 LOGIC CONTROL



The sample/hold mode control of the SMP-81 incorporates a unique logic input circuit, which enables direct interface to all popular logic families and provides maximum noise immunity. As shown in the figure, the mode control is accomplished by steering the current (I_1) through Q1 or Q2, thus providing high speed switching and a predictable logic threshold. For TTL and DTL interface, simply ground V_{LC} (pin 13). For CMOS, HTL and HNIL interface, the appropriate threshold voltage should be applied to V_{LC}.

For proper operation, the V_{LC} (logic reference) must be always at least 3.5V below the positive supply and 2.0V above the negative supply. Also, sample and hold control (S/H) must always be 2.8V above the negative supply.



ZERO SCALE ERROR NULL ADJUSTMENT

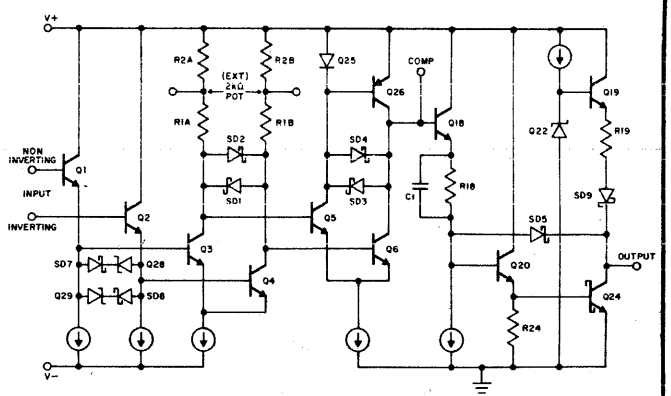
During the null adjustment, the amplifier should be switched continuously between the "sample" and "hold" mode. The error should then be adjusted to zero when the unit is in the "hold" mode. In this way, both offset voltage errors and charge transfer errors are adjusted to zero.

GUARDING AND GROUNDING LAYOUT

The use of a ground plane is strongly recommended to minimize ground path resistances. Separate analog and digital grounds should be used, and it is advisable to keep these two ground systems isolated until they are tied back to the common system ground. Digital currents should not flow back to the system ground through the analog ground path.

CMP-01

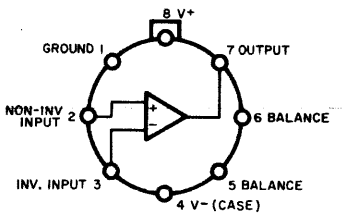
FAST PRECISION COMPARATOR



GENERAL DESCRIPTION

The CMP-01 is a monolithic Fast Precision Voltage Comparator using an advanced compatible NPN-Schottky Barrier Diode process. It features fast response time to both large and small input signals, while maintaining excellent input characteristics. The CMP-01 is capable of operating over a wide range of supply voltages, including single 5 volt supply operation. The large output current sinking and high output voltage capability assure good application flexibility, while the combination of fast response, high accuracy, and freedom from oscillation assure performance in precision level detectors and 12 and 13 bit A/D converters. The CMP-01 is pin compatible to earlier 111, 106, and 710 types. For applications requiring lower input offset and bias currents, refer to the CMP-02 data sheet.

FEATURES



- Fast Response Time . . . . . 110 ns typ., 180 ns Max
- High Input Slew Rate . . . . . .92 V/μS
- Low Offset Voltage . . . . . 0.3 mV typ., 0.8 mV Max
- Low Offset Current . . . . . 4 nA typ., 25 nA Max
- Low Offset Drift . . . . . 1.0 μV/°C, 30 pA/°C
- Standard Power Supplies . . . . . ±5V to ±18V
- Guaranteed Operation from Single +5V Supply
- No Pull-up Resistor Required for TTL Drive
- Wired OR Capability
- Fits 111, 106, 710 Sockets
- Easy Offset Nulling. . . . . Single 2kΩ Potentiometer
- Easy to Use. . . . . Free from Oscillations

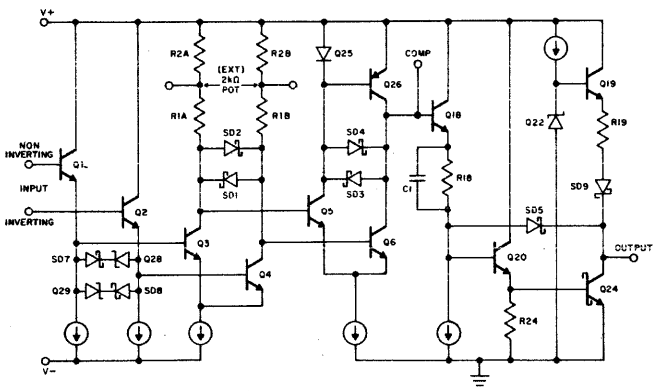
CMP-02

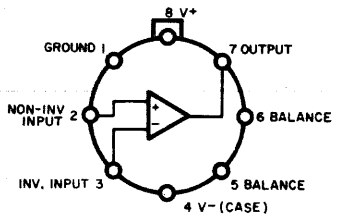
LOW INPUT CURRENT PRECISION COMPARATOR



GENERAL DESCRIPTION

The CMP-02 is a monolithic low input current comparator using an advanced compatible NPN-Schottky Barrier Diode process. It features superior input characteristics with extremely low offset voltage, offset current, bias current and temperature drift. High common mode and power supply rejection plus good response time contribute to excellent performance in the most demanding applications. The balanced offset nulling, large output drive, and wired-or capability combined with internal pull-up maximize application convenience. The CMP-02 is capable of operating over a wide range of supply voltages, including single plus 5 volt supply operation, and is pin-compatible to earlier 111, 106, and 710 types. For applications requiring faster response time, please refer to the CMP-01 Fast Precision Comparator data sheet.

FEATURES



- Low Offset Voltage . . . . . 0.3 mV typ., 0.8 mV Max
- Low Offset Current . . . . . 0.3 nA typ., 3.0 nA Max
- Low Bias Current . . . . . 28 nA typ., 50 nA Max
- Low Offset Drift . . . . . 1.0 μV/°C, 4 pA/°C
- High Gain . . . . . 200,000 Min
- High CMRR . . . . . 110 dB typ., 94 dB Min
- High Input Impedance . . . . . 16 MΩ
- Fast Response Time . . . . . 190 ns typ., 270 ns Max
- Standard Power Supplies . . . . . ±5V to ±18V
- Guaranteed Operation from Single +5V Supply
- No Pull-up Resistor Required for TTL Drive
- Wired-OR Capability
- Fits 111, 106, 710 Sockets
- Easy Offset Nulling . . . . . Single 2KΩ Potentiometer
- Easy to Use . . . . . Free from Oscillations

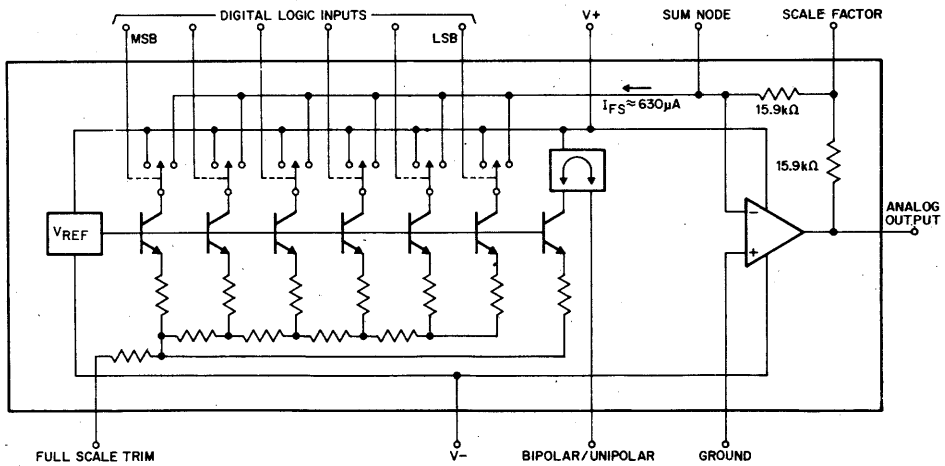
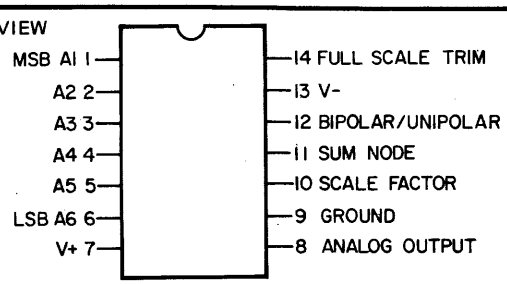
DAC-01

6 BIT MONOLITHIC D/A CONVERTER



GENERAL DESCRIPTION

The DAC-01 is a complete monolithic 6-bit digital-to-analog converter, incorporating current steering logic, current sources, diffused resistor ladder network, precision voltage reference and fast summing op amp on one chip. Monolithic construction provides small size, light weight, low power consumption and very high reliability. Wide power supply range, three output voltage options, and three input code options assure flexibility for a wide variety of applications. A seventh bit may also be added for greater resolution. The DAC-01 is ideal for CRT deflection circuits, servo positioning controls, digitally programmed power supplies and pulse generators, modem and telephone system digitizing and demodulation circuits, digital filters, and 6-bit A/D converters. Introduced in 1970, the DAC-01 is still the fastest, lowest power, most accurate 6-bit complete monolithic DAC ever made.



FEATURES

- Fast . . . . . 3μsec Settling Time (Max)
- Complete . . . . Includes Reference, Ladder, Op Amp
- Low Power Consumption . . . . . 250 mW (Max)
- 6-Bit Resolution . . . . . 7 Bit Accuracy
- 3 Output Options . . . . . +10V, ±5V, ±10V
- Standard Power Supplies . . . . . ±12V to ±18V
- −55°/+125°C or 0°/70°C Ranges Available
- TTL, DTL Compatible Logic Levels
- Models With MIL-STD-883A Class B Processing Available From Stock
- Low Cost

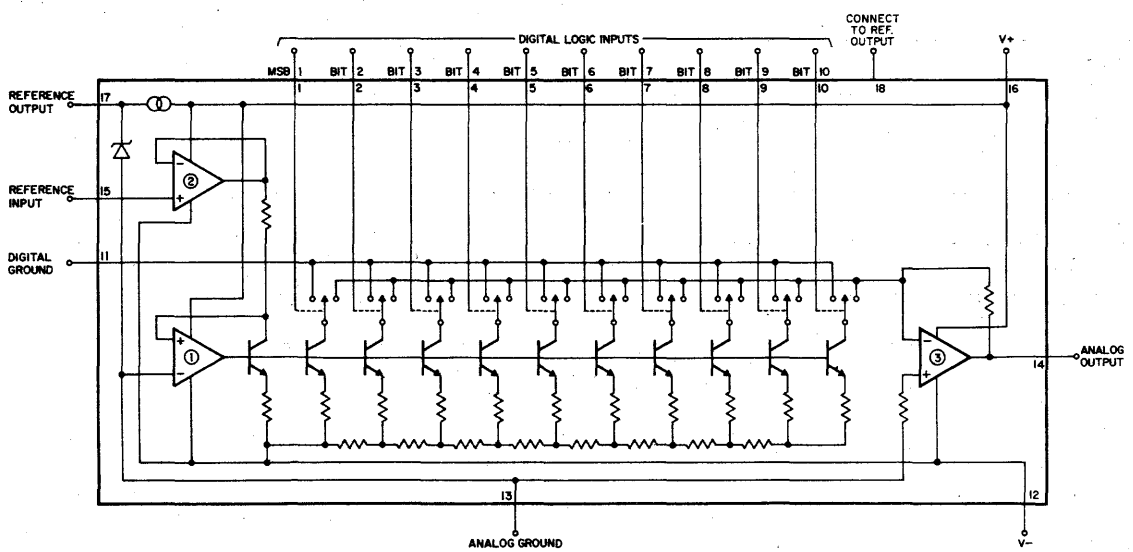
DAC-03

8 & 10 BIT LOW COST MONOLITHIC D/A CONVERTER



GENERAL DESCRIPTION

The DAC-03 is a complete 10 bit low cost D/A converter on a single 82 x 148 mil monolithic chip. All elements of a complete DAC are included—precision voltage reference, current steering logic, current sources, R-2R resistor network and high speed internally compensated output op amp. The untrimmed diffused R-2R resistor ladder network achieves monotonic operation over a wide temperature range. The buffered reference input is capable of tracking over a wide range of voltages, increasing application flexibility. The wide power supply range, low power consumption and choice of full scale output voltages assure utility in a wide range of applications including CRT displays, data acquisition systems, A/D converters, and servo positioning controls. For bipolar DAC's refer to the DAC-02 and DAC-04 data sheets.

FEATURES

- Monotonicity Guaranteed
- Low Cost
- Complete . . . . . Includes Reference and Op Amp
- Compact . . . . . Single 18 Pin DIP Package
- Fast . . . . . 1.5 μsec Settling Time
- Stable . . . . . Full Scale Tempco 60 ppm/°C
- Standard Power Supplies . . . . . ±12V to ±18V
- Low Power Consumption . . . . . 350 mW Max
- TTL, DTL, CMOS Compatible Inputs
- 5V and 10V Models Available

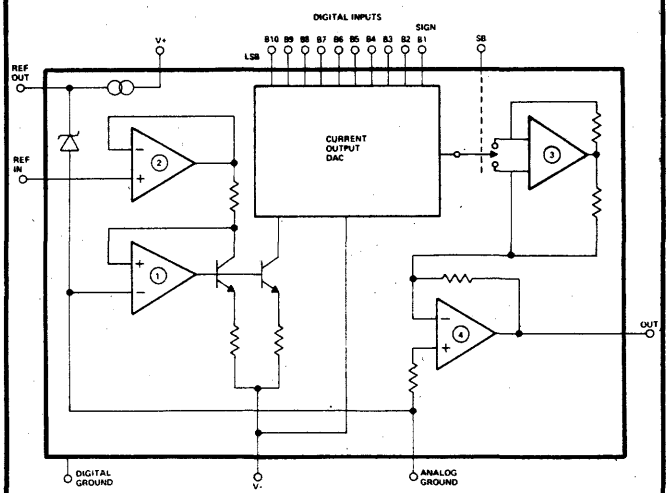
IMPROVED DAC-02

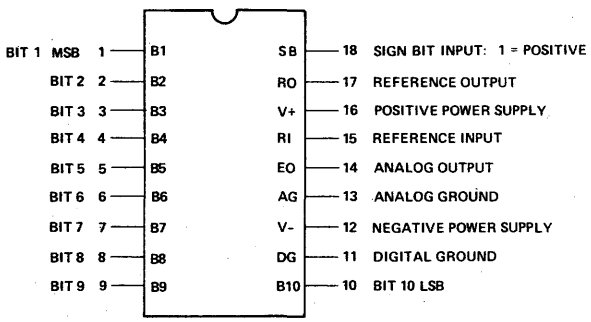
DAC-05

11 BIT DIGITAL TO ANALOG CONVERTER
(10 BITS PLUS SIGN)



GENERAL DESCRIPTION

The DAC-05 is a complete, monolithic, Sign Plus 10 Bit DAC with a voltage output. A precision voltage reference, a logic-controlled polarity switch, and a high speed (1.5 μsec settling time) output op amp are included. Monotonicity, non-linearity, power consumption, and full scale temperature coefficient are guaranteed over the full operating temperature range. Reliability is enhanced by a monolithic design, 100% burn-in, and a hermetic DIP package. Six low cost 0°/70°C and six -55°/+125°C models are available plus six models with MIL-STD-883A Class B processing.



FEATURES

- **Complete** ..... Includes Reference and Op Amp
- **Bipolar Output** ..... Sign/Magnitude Coding
- **Fast** ..... 1.5 μsec Settling Time
- **Monotonicity and Nonlinearity Guaranteed**
- **Reliable** ..... 100% Burned-in 72 Hrs @+125°C
- **Low Power Consumption** ..... 350 mW Max
- **Compact** ..... Single 18 Pin Hermetic DIP Package
- **Choice of Output Ranges** ..... ±5V or ±10V
- **Models with MIL-STD-883A Class B Processing Available From Stock**

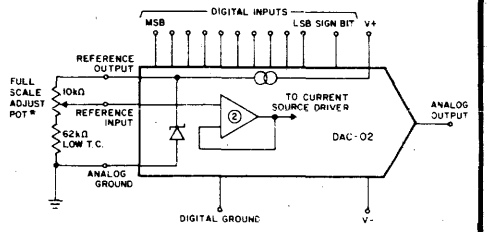
NOTE 2: Zero Scale Symmetry is the change in the output voltage produced by switching the Sign Bit with all logic bits low (V_{ZS+} -V_{ZS-}).

NOTE 3: Full Scale Bipolar Symmetry is the magnitude of the difference between $|V_{FS+}|$ and $|V_{FS-}|$.

©IC MASTER 1978



CONNECTION INFORMATION

FULL SCALE ADJUSTMENT - Full Scale output voltage may be trimmed by use of a potentiometer and series resistor as shown; however, best results will be obtained if a low tempco resistor is used or if pot and resistor tempcos match. Alternatively, a single pot of ⩾ 75KΩ may be used.

REFERENCE INPUT BYPASS - Lowest noise and fastest settling operation will be obtained by bypassing the Reference Input to Analog Ground with a 0.01μF disk capacitor

GROUNDING - For optimum noise rejection, separate digital and analog grounds have been brought out. Best results will be obtained if these grounds are connected together at one point only, preferably near the DAC-05 package, so that the large digital currents do not flow through the analog ground path.

NOTE 1: Reference Output terminal connected directly to Reference Input terminal, R_L = 2KΩ, all logic inputs ⩾ 2.0 V.

NOTE 2: Zero Scale Symmetry is the change in the output voltage produced by switching the Sign Bit with all logic bits low (V_{ZS+} -V_{ZS-}).

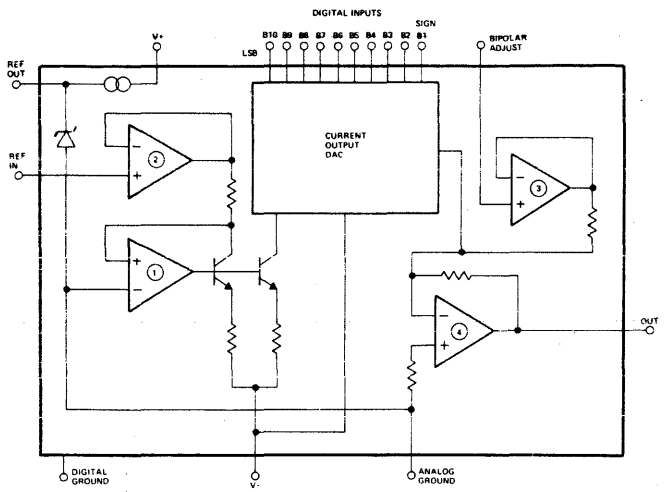
NOTE 3: Full Scale Bipolar Symmetry is the magnitude of the difference between $|V_{FS+}|$ and $|V_{FS-}|$.

NOTE 4: Parameter is not 100% tested; 90% of units meet this specification.

IMPROVED DAC-04

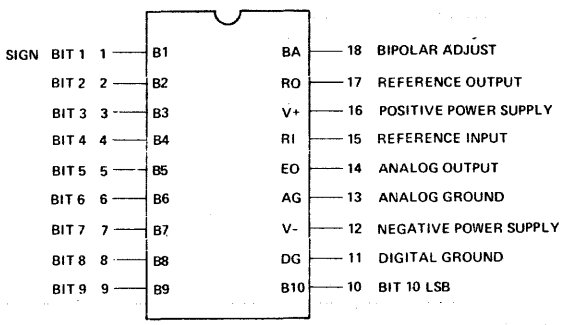
DAC-06

TWO'S COMPLEMENT 10 BIT D/A CONVERTER



GENERAL DESCRIPTION

The DAC-06 is a complete, monolithic, Two's Complement 10 Bit DAC with a voltage output. A precision voltage reference, R-2R resistor network, bipolar offset circuit, and a high speed (1.5 μsec settling time) output op amp are included. Monotonicity, nonlinearity, power consumption, and full scale temperature coefficient are guaranteed over the full operating temperature range. Reliability is enhanced by a monolithic design, 100% burn-in, and a hermetic DIP package. Three low cost 0°/70°C and three -55°/+125°C models are available plus three models with MIL-STD-883A Class B processing.



FEATURES

- Complete . . . . . Includes Reference and Op Amp
- Bipolar Output . . . . . Two's Complement Coding
- Fast . . . . . 1.5 μsec Settling Time
- Monotonicity and Nonlinearity Guaranteed
- Reliable . . . . . 100% Burned-in 72 Hrs @ +125°C
- Low Power Consumption . . . . . 350 mW Max
- Compact . . . . Single 18 Pin Hermetic DIP Package
- Models with MIL-STD-883A Class B Processing Available From Stock

DAC-06 DEFINITIONS

FULL SCALE OUTPUT RANGE—The peak-to-peak voltage swing of the converter's output, i.e. $|V_{FS+}|+|V_{FS-}|$ for bipolar operation, and (V_{FS}-V_{ZS}) for unipolar operation.

POSITIVE BIPOLAR FULL SCALE OUTPUT VOLTAGE (V_{FS+})—The output for 0111111111 input code.

NEGATIVE BIPOLAR FULL SCALE OUTPUT VOLTAGE(V_{FS-})—The output voltage for 1000000001 input code for Two's Complement coding, or the output voltage for 1000000000 input code for One's Complement coding.

UNIPOLAR FULL SCALE OUTPUT VOLTAGE (V_{FS})—The (positive) output voltage for 0111111111 input code.

UNIPOLAR ZERO SCALE OUTPUT VOLTAGE (V_{ZS})—The output voltage for 1000000000 input code.

BIPOLAR OFFSET VOLTAGE 1/2($|V_{FS+}|-|V_{FS-}|$)—The maximum error due to asymmetry around zero output expressed as a percentage of Full Scale Output Range. (This is adjustable to zero—see Adjustment Procedures on the last page.)

LEAST SIGNIFICANT BIT (LSB)—The smallest incremental output change obtainable, which is ideally equal to the full scale output range divided by 2^{n-1}, where n = number of bits of resolution.

MOST SIGNIFICANT BIT (MSB)—The largest incremental output change obtainable by switching a single logic input, ideally equal to the ideal LSB multiplied by 2^{n-1}, where n = number of bits of resolution. In Two's and One's Complement Converters this MSB is inverted with respect to the other (binary) bits and is used as a sign bit; this feature is incorporated into the DAC-06 design.

MONOTONICITY—Having each successive output state greater than or equal to the preceding one when the DAC is sequenced through all successive states from V_{FS-} to V_{FS+}.

FULL SCALE TEMPERATURE COEFFICIENT—Change in absolute full scale output range in ppm between 25°C and either temperature extreme divided by the corresponding change in temperature.

POWER SUPPLY SENSITIVITY—The ratio of the percentage change in full scale output range to the change in the supply voltage producing it.

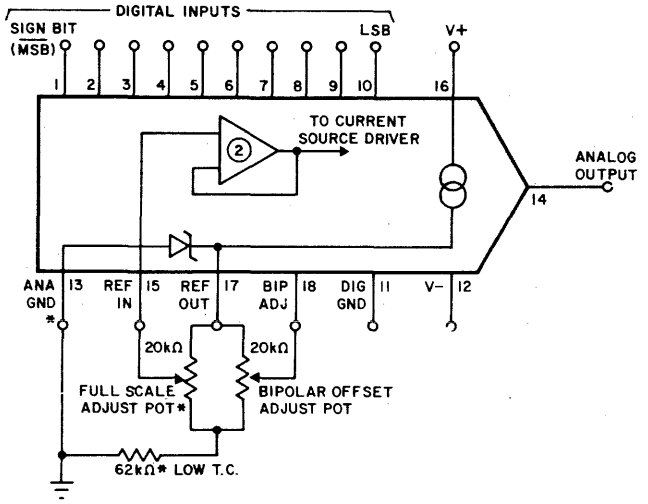
CONNECTION INFORMATION

EXTERNAL ADJUSTMENTS - Full Scale Range and Bipolar Symmetry may be adjusted using the connections shown with the procedures on the next page.

REFERENCE INPUT BYPASS - Lowest noise and fastest settling operation will be obtained by bypassing the Reference Input and the Bipolar Offset Adjust inputs with 0.01μF disc capacitors connected to Analog Ground.



GROUNDING - For optimum noise rejection, separate digital and analog grounds have been brought out. Best results will be obtained if these grounds are connected together at one point only, preferably at the DAC-06 package, so that large digital currents do not flow through the analog ground path.

REFERENCE OUTPUT - For best results, Reference Output current should not exceed 100μA.

USE WITH EXTERNAL REFERENCES - Positive-polarity external reference voltages referred to Analog Ground may be applied to the Reference Input terminal to improve full scale tempco, to provide tracking to other system elements, or to slave a number of DAC-06's to the Reference Output of any one of them.

UNIPOLAR OPERATION - Operation as a 10V positive output 10 bit converter may be implemented by permanently tying pin 18 to ground.

LOWER RESOLUTION APPLICATIONS - For applications not requiring full 10 bit resolution, unused logic inputs should be tied to ground.

NOTE: For unipolar operation, omit the Bipolar offset adjustment potentiometer.

IMPROVED 1408A/1508A

DAC-08

8 BIT HIGH SPEED MULTIPLYING D/A CONVERTER

UNIVERSAL DIGITAL LOGIC INTERFACE

GENERAL DESCRIPTION

The DAC-08 series of 8 bit monolithic multiplying Digital-to-Analog Converters provide very high speed performance coupled with low cost and outstanding applications flexibility.

Advanced circuit design*achieves 85 nsec settling times with very low "glitch" and at low power consumption. Monotonic multiplying performance is attained over a wide 40 to 1 reference current range. Matching to within 1 LSB between reference and full scale currents eliminates the need for full scale trimming in most applications. Direct interface to all popular logic families with full noise immunity is provided by the high swing, adjustable threshold logic inputs.

High voltage compliance dual complementary current outputs are provided, increasing versatility and enabling differential operation to effectively double the peak-to-peak output swing. In many applications, the outputs can be directly converted to voltage without the need for an external op amp.

All DAC-08 series models guarantee full 8 bit monotonicity, and nonlinearities as tight as ±0.1%over the entire operating temperature range are available. Device performance is essentially unchanged over the ±4.5V to ±18V power supply range, with 33 mW power consumption attainable at ±5V supplies.

FEATURES

- Fast Settling Output Current . . . . . 85 nsec
- Full Scale Current Prematched to ±1 LSB
- Direct Interface to TTL, CMOS, ECL, HTL, PMOS
- Nonlinearity to ±0.1% Max Over Temp Range
- High Output Impedance and Compliance . . −10V to +18V
- Differential Current Outputs
- Wide Range Multiplying Capability . . . . 1 MHz Bandwidth
- Low FS Current Drift . . . . . ±10ppm/°C
- Wide Power Supply Range . . . . . ±4.5V to ±18V
- Low Power Consumption . . . . . 33 mW @ ±5V
- Low Cost

The compact size and low power consumption make the DAC-08 attractive for portable and military/aerospace applications; devices processed to MIL-STD-883A, Level B are available.

DAC-08 applications include 8 bit, 1 μsec A/D converters, servo-motor and pen drivers, waveform generators, audio encoders and attenuators, analog meter drivers, programmable power supplies, CRT display drivers, high speed modems and other applications where low cost, high speed and complete input/output versatility are required.

APPLICATIONS INFORMATION

REFERENCE AMPLIFIER SETUP

The DAC-08 is a multiplying D/A converter in which the output current is the product of a digital number and the input reference current. The reference current may be fixed or may vary from nearly zero to +4.0mA. The full scale output current is a linear function of the reference current and is given by:

$$I_{FS} = \frac{255}{256} \times I_{REF} \text{ where } I_{REF} = I_{14}.$$

In positive reference applications (Fig. 18), an external positive reference voltage forces current through R_{14} into the $V_{REF(+)}$ terminal (pin 14) of the reference amplifier. Alternatively, a negative reference may be applied to $V_{REF(-)}$ at pin 15 (Fig. 20); reference current flows from ground through R_{14} into $V_{REF(+)}$ as in the positive reference case. This negative reference connection has the advantage of a very high impedance presented at pin 15. The voltage at pin 14 is equal to and tracks the voltage at pin 15 due to the high gain of the internal reference amplifier. R_{15} (nominally equal to R_{14}) is used to cancel bias current errors; R_{15} may be eliminated with only a minor increase in error.

Bipolar references may be accomodated by offsetting V_{REF} or pin 15 as shown in Fig. 28. The negative common mode range of the reference amplifier is given by: V_{CM-} = V− plus ($I_{REF} \times 1\,K\Omega$) plus 2.5V. The positive common mode range is V+ less 1.5V.

When a DC reference is used, a reference bypass capacitor is recommended. A 5.0V TTL logic supply is not recommended as a reference. If a regulated power supply is used as a reference, R_{14} should be split into two resistors with the junction bypassed to ground with a 0.1 μF capacitor.

For most applications, a +10.0V reference is recommended for optimum full scale temperature coefficient performance. This will minimize the contributions of reference amplifier V_{OS} and TCV_{OS}. For most applications the tight relationship between I_{REF} and I_{FS} will eliminate the need for trimming I_{REF}. If required, full scale trimming may be accomplished by adjusting the value of R_{14}, or by using a potentiometer for R_{14}. An improved method of full scale trimming which eliminates potentiometer T.C. effects in shown in Fig. 19.

Using lower values of reference current reduces negative power supply current and increases reference amplifier negative common mode range. The recommended range for operation with a DC reference current is +0.2mA to +4.0mA.

The reference amplifier must be compensated by using a capacitor from pin 16 to V−. For fixed reference operation, a 0.01 μF capacitor is recommended. For variable reference applications, see section entitled "Reference Amplifier Compensation for Multiplying Applications."

MULTIPLYING OPERATION

The DAC-08 provides excellent multiplying performance with an extremely linear relationship between I_{FS} and I_{REF} over a range of 4 mA to 4 μA. Monotonic operation is maintained over a typical range of I_{REF} from 100 μA to 4.0 mA; consult factory for devices selected for monotonic operation over wider I_{REF} ranges.

REFERENCE AMPLIFIER COMPENSATION FOR MULTIPLYING APPLICATIONS

AC reference applications will require the reference amplifier to be compensated using a capacitor from pin 16 to V−. The value of this capacitor depends on the impedance presented to pin 14: for R_{14} values of 1.0, 2.5 and 5.0 KΩ, minimum values of C_c are 15, 37, and 75 pF. Larger values of R_{14} require proportionately increased values of C_c for proper phase margin.

For fastest response to a pulse, low values of R_{14} enabling small C_c values should be used. If pin 14 is driven by a high impedance such as a transistor current source, none of the above values will suffice and the amplifier must be heavily compensated which will decrease overall bandwidth and slew rate. For R_{14} = 1 KΩ and C_c = 15 pF, the reference amplifier slews at 4 mA/μsec enabling a transition from I_{REF} = 0 to I_{REF} = 2 mA in 500 nsec.

Operation with pulse inputs to the reference amplifier may be accomodated by an alternate compensation scheme shown in Fig. 27. This technique provides lowest full scale transition times. An internal clamp allows quick recovery of the reference amplifier from a cutoff (I_{REF} = 0) condition. Full scale transition (0 to 2 mA) occurs in 120 nsec when the equivalent impedance at pin 14 is 200 Ω and C_c = 0. This yields a reference slew rate of 16 mA/μsec which is relatively independent of R_{IN} and V_{IN} values.

LOGIC INPUTS

The DAC-08 design incorporates a unique logic input circuit which enables direct interface to all popular logic families and provides maximum noise immunity. This feature is made possible by the large input swing capability, 2μA logic input current and completely adjustable logic threshold voltage. For V− = −15V, the logic inputs may swing between −10V and +18V. This enables direct interface with +15V CMOS logic, even when the DAC-08 is powered from a +5V supply. Minimum input logic swing and minimum logic threshold voltage are given by: V− plus ($I_{REF} \times 1\,K\Omega$) plus 2.5V. The logic threshold may be adjusted over a wide range by placing an appropriate voltage at the logic threshold control pin (pin 1, V_{LC}). Fig. 11 shows the relationship between V_{LC} and V_{TH} over the temperature range, with V_{TH} nominally 1.4 above V_{LC}. For TTL and DTL interface, simply ground pin 1. When interfacing ECL, an I_{REF} = 1 mA is recommended. For interfacing other logic families, see Fig. 26. For general setup of the logic control circuit, it should be noted that pin 1 will source 100 μA typical; external circuitry should be designed to accommodate this current.

Fastest settling times are obtained when pin 1 sees a low impedance. If pin 1 is connected to a 1 KΩ divider, for example, it should be bypassed to ground by a 0.01 μF capacitor.

©IC MASTER 1978

ANALOG OUTPUT CURRENTS

Both true and complemented output sink currents are provided, where $I_O + \overline{I_O} = I_{FS}$. Current appears at the "true" output when a "1" is applied to each logic input. As the binary count increases, the sink current at pin 4 increases proportionally, in the fashion of a "positive logic" D/A converter. When a "0" is applied to any input bit, that current is turned off at pin 4 and turned on at pin 2. A decreasing logic count increases $\overline{I_O}$ as in a negative or inverted logic D/A converter. Both outputs may be used simultaneously. If one of the outputs is not required it must still be connected to ground or to a point capable of sourcing I_{FS}; do not leave an unused output pin open.

Both outputs have an extremely wide voltage compliance enabling fast direct current-to-voltage conversion through a resistor tied to ground or other voltage source. Positive compliance is 36V above V− and is independent of the positive supply. Negative compliance is given by V− plus (I_{REF} X1 KΩ) plus 2.5V.

The dual outputs enable double the usual peak-to-peak load swing when driving loads in quasi-differential fashion. This feature is especially useful in cable driving, CRT deflection and in other balanced applications such as driving center-tapped coils and transformers.

POWER SUPPLIES

The DAC-08 operates over a wide range of power supply voltages from a total supply of 9V to 36V. When operating at supplies of ±5V or less, $I_{REF} \leq 1$ mA is recommended. Low reference current operation decreases power consumption and increases negative compliance, reference amplifier negative common mode range, negative logic input range, and negative logic threshold range; consult the various figures for guidance. For example, operation at −4.5V with I_{REF} = 2 mA is not recommended because negative output compliance would be reduced to near zero. Operation from lower supplies is possible, however at least 8V total must be applied to insure turn-on of the internal bias network.

Symmetrical supplies are not required, as the DAC-08 is quite insensitive to variations in supply voltage. Battery operation is feasible as no ground connection is required; however, an artificial ground may be useful to insure logic swings, etc. remain between acceptable limits.

Power consumption may be calculated as follows:

$P_d = (I+)\ (V+) + (I+)\ (V-) + (2\ I_{REF})\ (V-)$. A useful feature of the DAC-08 design is that supply current is constant and independent of input logic states; this is useful in cryptographic applications and further serves to reduce the size of the power supply bypass capacitors.

TEMPERATURE PERFORMANCE

The nonlinearity and monotonicity specifications of the DAC-08 are guaranteed to apply over the entire rated operating temperature range. Full scale output current drift is tight, typically ±10 ppm/°C, with zero scale output current and drift essentially negligible compared to 1/2 LSB.

Full scale output drift performance will be best with +10.0V references as V_{OS} and TCV_{OS} of the reference amplifier will be very small compared to 10.0V. The temperature coefficient of the reference resistor R_{14} should match and track that of the output resistor for minimum overall full scale drift. Settling times of the DAC-08 decrease approximately 10% at −55°C; at +125°C an increase of about 15% is typical.

SETTLING TIME

The DAC-08 is capable of extremely fast settling times, typically 85 nsec at I_{REF} = 2.0 mA. Judicious circuit design and careful board layout must be employed to obtain full performance potential during testing and application. The logic switch design enables propagation delays of only 35 nsec for each of the 8 bits. Settling time to within 1/2 LSB of the LSB is therefore 35 nsec, with each progressively larger bit taking successively longer. The MSB settles in 85 nsec, thus determining the overall settling time of 85 nsec. Settling to 6-bit accuracy requires about 65 to 70 nsec. The output capacitance of the DAC-08 including the package is approximately 15 pF, therefore the output RC time constant dominates settling time if $R_L > 500\Omega$.

Settling time and propagation delay are relatively insensitive to logic input amplitude and rise and fall times, due to the high gain of the logic switches. Settling time also remains essentially constant for I_{REF} values down to 1.0 mA, with gradual increases for lower I_{REF} values. The principal advantage of higher I_{REF} values lies in the ability to attain a given output level with lower load resistors, thus reducing the output RC time constant.

Measurement of settling time requires the ability to accurately resolve ±4 μA, therefore a 1 KΩ load is needed to provide adequate drive for most oscilloscopes. The settling time fixture of Fig. 29 uses a cascode design to permit driving a 1 KΩ load with less than 5pF of parasitic capacitance at the measurement node. At I_{REF} values of less than 1.0 mA, excessive RC damping of the output is difficult to prevent while maintaining adequate sensitivity. However, the major carry from 01111111 to 10000000 provides an accurate indicator of settling time. This code change does not require the normal 6.2 time constants to settle to within ±0.2% of the final value, and thus settling times may be observed at lower values of I_{REF}.

DAC-08 switching transients or "glitches" are very low and may be further reduced by small capacitive loads at the output at a minor sacrifice in settling time.

Fastest operation can be obtained by using short leads, minimizing output capacitance and load resistor values, and by adequate bypassing at the supply, reference and V_{LC} terminals. Supplies do not require large electrolytic bypass capacitors as the supply current drain is independent of input logic states; 0.1 μF capacitors at the supply pins provide full transient protection.

PRELIMINARY

DAC-10

10 BIT HIGH SPEED MULTIPLYING D/A CONVERTER
UNIVERSAL DIGITAL LOGIC INTERFACE

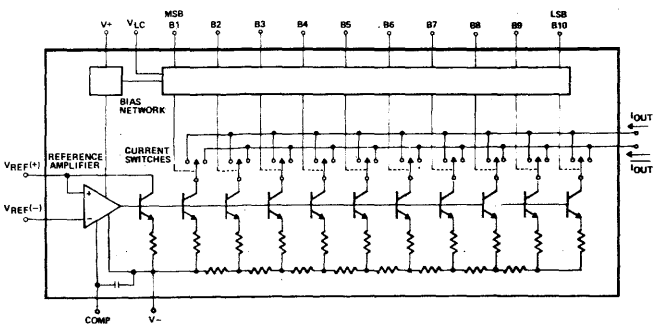
GENERAL DESCRIPTION

The DAC-10 series of 10 bit monolithic multiplying Digital-to-Analog Converters provide high speed performance and full scale accuracy.

Advanced circuit design achieves 250nsec settling times with very low 'glitch' and at low power consumption. Matching to within 1 LSB between reference and full scale currents eliminates the need for full scale trimming in most applications. Direct interface to all popular logic families with full noise immunity is provided by the high swing, adjustable threshold logic inputs.

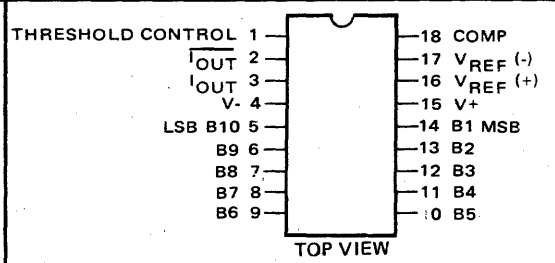
High voltage compliance dual complementary current outputs are provided, increasing versatility and enabling differential operation to effectively double the peak-to-peak output swing. In many applications, the outputs can be directly converted to voltage without the need for an external op amp.

All DAC-10 series models guarantee full 10 bit monotonicity, and nonlinearities as tight as ±.05% over the entire operating temperature range are available. Device performance is essentially unchanged over the ±4.5V to ±18V power supply range, with 75mW power consumption attainable at lower supplies.



A 'Field Proven' unique trim method is used, which selectively shorts zener diodes, to provide 1/4 LSB full scale accuracy without the need for laser trimming.

FEATURES



- **Fast Settling Output Current 250nsec**
- **Full Scale Current Prematched to ±1 LSB**
- **Direct Interface to TTL, CMOS, ECL, HTL, PMOS**
- **Nonlinearity to ±0.025% Full Scale**
- **High Output Impedance and True Compliance ±10V**
- **Differential Current Outputs**
- **Wide Range Multiplying Capability . . . . 1 MHz Bandwidth**
- **Low FS Current Drift . . . . . ± 6 ppm/°C**
- **Wide Power Supply Range . . . . . ±4.5V to ±18V**
- **Low Power Consumption 75mW**
- **Low Cost**

Single chip reliability coupled with low cost and outstanding flexibility make the DAC-10 devices ideal building blocks in A/D converters, Data Acquisition systems, CRT display, programmable test equipment, and other applications where low power consumption and complete input/output versatility are required.

DAC-12/30

12 BIT HIGH SPEED MULTIPLYING D/A CONVERTER
UNIVERSAL DIGITAL LOGIC INTERFACE

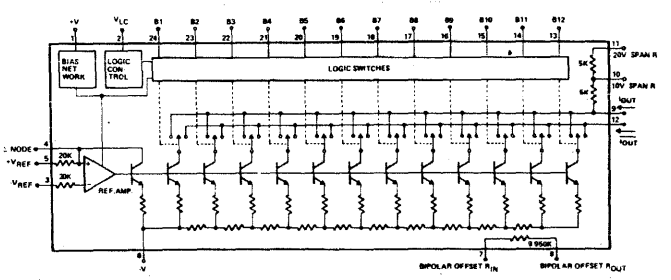
GENERAL DESCRIPTION

The DAC-12/30 series of 12 bit monolithic multiplying Digital-to-Analog converters offers the DAC-12 for straight binary or offset binary applications, and the DAC-30 for BCD code requirements.

Advanced circuit design achieves 750nsec settling times with very low 'glitch' and at low power consumption. Matching to within 1 LSB between reference and full scale currents eliminates the need for full scale trimming in most applications. Direct interface to all popular logic families with full noise immunity is provided by the high swing, adjustable threshold logic inputs.

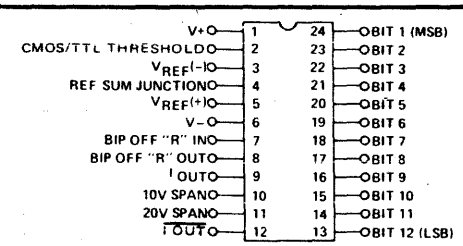
High voltage compliance dual complementary current outputs are provided, increasing versatility and enabling differential operation to effectively double the peak-to-peak output swing. In many applications, the outputs can be directly converted to voltage without the need for an external op amp.

All DAC-12 series models guarantee full 12 bit monotonicity, and nonlinearities as tight as ±.02% over the entire operating temperature range are available. Device performance is essentially unchanged over the +4.5V/-10V to ±18V power supply range, with 150mW power consumption attainable at lower supplies.



FEATURES

- True Monolithic Construction
- Fast Settling Output Current 750nsec
- Full Scale Current Prematched to ±1 LSB
- Direct Interface to TTL, CMOS, ECL, HTL, PMOS
- True 12-Bit Linearity . . . . . ±0.25LSB
- High Output Impedance and True Compliance . . . . . ±5V
- Differential Current Outputs
- High Speed Multiplying Capability
- Low FS Current Drift . . . . . ± 6 ppm/°C
- Wide Power Supply Range . . . . . +4.5V/-10V to ±18V
- Low Power Consumption 150mW
- Trimmed for Linearity after Package is Sealed



A field proven unique trim method is used, which selectively shorts zener diodes, to provide 1/4 LSB full scale accuracy on DAC-12 models without the need for laser trimming.

High speed and precision accuracy coupled with single chip reliability, low cost and outstanding flexibility make the DAC-12/30 devices ideal building blocks in A/D converters, Data Acquisition systems, CRT displays, programmable test equipment, and other applications where low power consumption and complete input/output versatility are required.

DAC-20

2 DIGIT BCD HIGH SPEED MULTIPLYING DAC
UNIVERSAL DIGITAL LOGIC INTERFACE

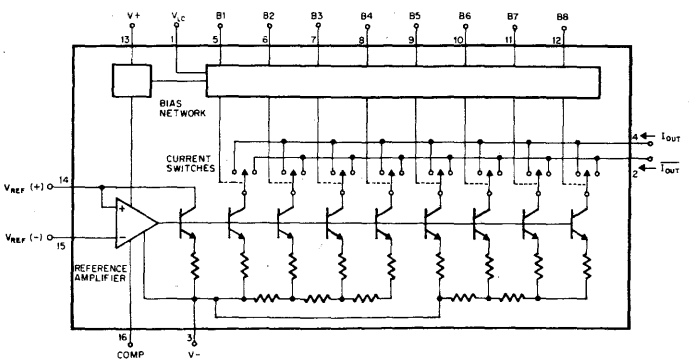
GENERAL DESCRIPTION

The DAC-20 series of 2 digit BCD monolithic multiplying Digital-to-Analog Converters provide very high speed performance coupled with low cost and outstanding applications flexibility.

Advanced circuit design* achieves 85 nsec settling times with very low "glitch" and at low power consumption. Monotonic multiplying performance is attained over a wide 40 to 1 reference current range. Matching to within 1 LSB between reference and full scale currents eliminates the need for full scale trimming in most applications. Direct interface to all popular logic families with full noise immunity is provided by the high swing, adjustable threshold logic inputs.

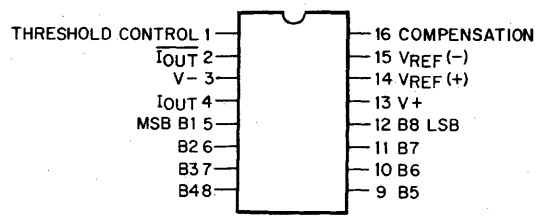
Dual complementary current outputs with -10V to +18V voltage compliance enable resistive termination, a voltage output without an external op amp.

All DAC-20 series models guarantee full 2 digit monotonicity, and nonlinearities as tight as ±¼ LSB over the entire operating temperature range are available. Nonlinearity is unchanged over the ±4.5V to ±18V power supply range, with 37mW power consumption attainable at ±5V supplies.



FEATURES

- Fast Settling Output Current . . . . . 85 nsec
- Full Scale Current Prematched to ±1 LSB
- Direct Interface to TTL, CMOS, ECL, HTL, PMOS
- Nonlinearity to ±¼ LSB Max Over Temp Range
- High Output Impedance and Compliance . . -10V to +18V
- Complementary Current Outputs
- Wide Range Multiplying Capability . . . . 1 MHz Bandwidth
- Low FS Current Drift . . . . . ±10ppm/°C
- Wide Power Supply Range . . . . . ±4.5V to ±18V
- Low Power Consumption . . . . . 37mW @ ±5V
- Low Cost



The compact size and low power consumption make the DAC-20 attractive for portable and military/aerospace applications; devices processed to MIL-STD-883A, Level B, are available.

DAC-20 applications include A/D converters, audio attenuators, analog meter drivers, programmable power supplies, high speed modems and other applications where low cost, high speed and complete input/output versatility are required.

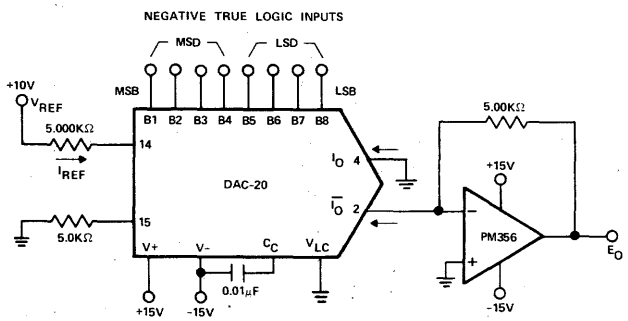
BASIC OUTPUT CONNECTIONS

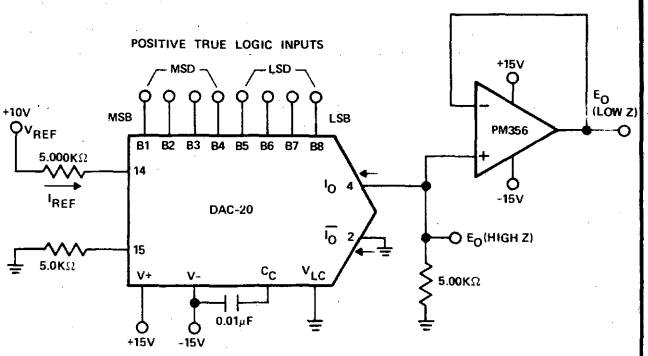
With complementary current outputs, the DAC-20 may be used with either positive true or negative true (complementary) logic. Current appears at the "true" output (I_O) when a "1" is applied to a logic input. As the BCD-coded input increases, the sink current at pin 4 increases proportionately, in the fashion of a "positive logic" D/A converter. When a "0" is applied to a logic input, that current is turned off at pin 4 and on at pin 2 ($\overline{I_O}$) which is used for negative true or "negative logic" D/A converters.



The unused output must be connected to ground or some voltage source capable of sourcing 1.65 times I_{REF}. A detailed discussion of reference input operation begins on the next page.

Both outputs have an extremely wide voltage compliance enabling fast direct current-to-voltage conversion through a resistor tied to ground or other voltage source. Positive compliance is 36V above V- and is independent of the positive supply. Negative compliance is given by V- plus (I_{REF} X800Ω) plus 2.5V.

POSITIVE VOLTAGE OUTPUT



NORMALIZED INPUT	DIGITAL INPUT MSD	DIGITAL INPUT LSD	I_O	E_O
0	0000	0000	0	0

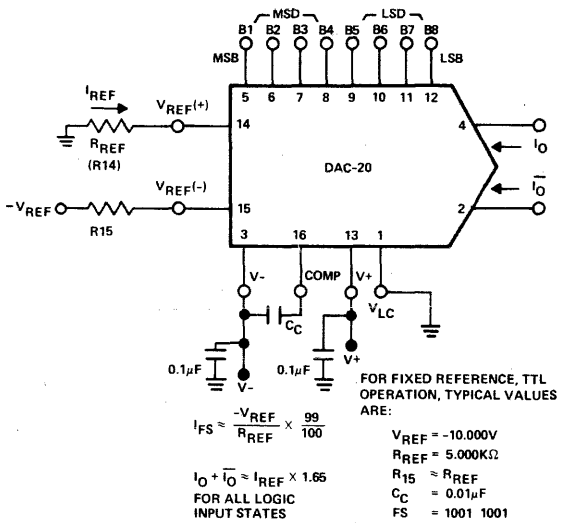
REFERENCE OPERATION

POSITIVE

$$I_{FS} \approx \frac{+V_{REF}}{R_{REF}} \times \frac{99}{100}$$



$I_O + \overline{I_O} \approx I_{REF} \times 1.65$

FOR ALL LOGIC INPUT STATES

FOR FIXED REFERENCE, TTL OPERATION, TYPICAL VALUES ARE:

$V_{REF} = +10.000V$
$R_{REF} = 5.000K\Omega$
$R_{15} \approx R_{REF}$
$C_C = 0.01\mu F$
FS = 1001 1001

NEGATIVE

$$I_{FS} \approx \frac{-V_{REF}}{R_{REF}} \times \frac{99}{100}$$

$I_O + \overline{I_O} \approx I_{REF} \times 1.65$

FOR ALL LOGIC INPUT STATES

FOR FIXED REFERENCE, TTL OPERATION, TYPICAL VALUES ARE:

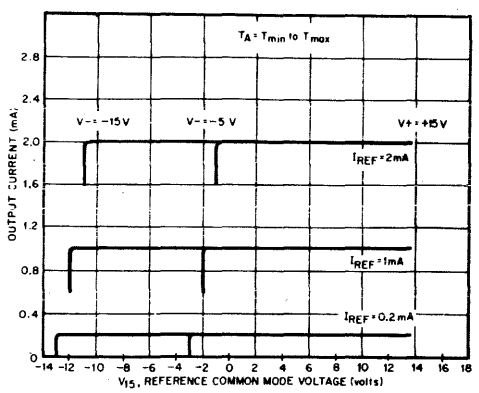
$V_{REF} = -10.000V$
$R_{REF} = 5.000K\Omega$
$R_{15} \approx R_{REF}$
$C_C = 0.01\mu F$
FS = 1001 1001

REFERENCE AMPLIFIER SETUP

The DAC-20 is a multiplying D/A converter in which the output current is the product of a digital number and the input reference current. The reference current may be fixed or may vary from nearly zero to +4.0mA. The full scale output current is a linear function of the reference current and is given by:

$$I_{FS} = 99/100 \times I_{REF} \text{ where } I_{REF} = I_{14}.$$

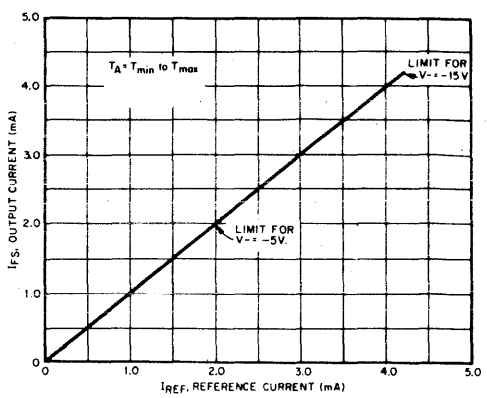
In positive reference applications an external positive reference voltage forces current through R_{14} into the $V_{REF}(+)$ terminal (pin 14) of the reference amplifier. Alternatively, a negative reference may be applied to $V_{REF}(-)$ at pin 15; reference current flows from ground through R_{14} into $V_{REF}(+)$ as in the positive reference case. This negative reference connection has the advantage of a very high impedance presented at pin 15. The voltage at pin 14 is equal to and tracks the voltage at pin 15 due to the high gain of the internal reference amplifier. R_{15} (nominally equal to R_{14}) is used to cancel bias current errors and may be eliminated with only a minor increase in error.



When a DC reference is used, a reference bypass capacitor is recommended. A 5.0V TTL logic supply is not recommended as a reference. If a regulated power supply is used as a reference, R_{14} should be split into two resistors with the junction bypassed to ground with a 0.1μF capacitor.

For most applications, a +10.0V reference such as the PMI REF-01 is recommended for optimum full scale temperature coefficient performance. This will minimize the contributions of reference amplifier V_{OS} and TCV_{OS}. For most applications the tight relationship between I_{REF} and I_{FS} will eliminate the need for trimming I_{REF}. If required, full scale trimming may be accomplished by adjusting the value of R14.

The reference amplifier must be compensated by using a capacitor from pin 16 to V-. For fixed reference operation, a 0.01 μF capacitor is recommended. For variable reference applications, see section entitled "Multiplying Operation."



TYPICAL REFERENCE PERFORMANCE CURVES

REFERENCE AMP COMMON MODE RANGE (DIGITAL INPUT 1001 1001)

NOTE: Positive common mode range is always (V+)−1.5V; negative common mode range is V- plus(I_{REF} X 800Ω) plus 2.5V.

FULL SCALE CURRENT VS. REFERENCE CURRENT (DIGITAL INPUT 1001 1001)

NOTE: The recommended range for operation with a DC reference current is +0.2mA to +4.0mA.

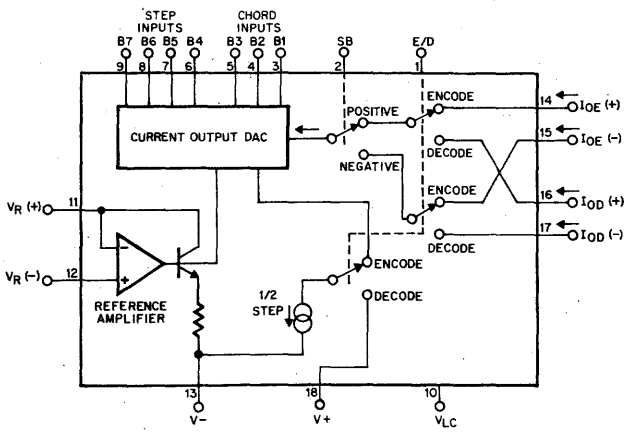
DAC-76

COMDAC™ COMPANDING D/A CONVERTER

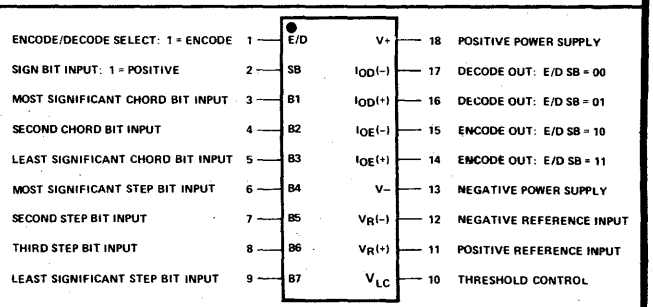
MONOLITHIC LOGARITHMIC DAC

FEATURES

- Sign Plus 12 Bit Range With Sign Plus 7 Bit Coding
- 12 Bit Accuracy and Resolution Around Zero
- Sign Plus 72dB Dynamic Range
- True Current Outputs: –5V to +18V Compliance
- Tight Full Scale Tolerance Eliminates Calibration
- Low Full Scale Drift Over Temperature
- Conforms With Bell System μ-255 Companding Law
- Multiplying Reference Inputs
- Low Power Consumption and Low Cost
- Ideal for PCM, Audio, and 8 Bit μP Applications
- Outputs Multiplexed for Time Shared Applications



GENERAL DESCRIPTION



The DAC-76 monolithic COMDAC™ D/A Converter provides the dynamic range of a sign + 12-bit DAC in a sign + 7-bit format. A companding (compression/expansion) transfer function is implemented by using three bits to select one of eight binarily-related chords (or segments) and four bits to select one of sixteen linearly-related steps within each chord. Accuracy is assured by specifying chord end point values, chord nonlinearity, and monotonicity over the full operating temperature range.

The 8-bit format with a sign + 72dB dynamic range is especially useful in control systems using 8-bit microprocessors, RAM's and ROM's. Low distortion multiplying capability and conformance with the Bell System μ-255 logarithmic law for PCM transmission make the DAC-76 ideal for use in audio applications. Other applications include servo controls, stress and vibration analysis, digital recording and speech synthesis. Additional applications are listed on the last page.

COMPANDING PRINCIPLES

BACKGROUND

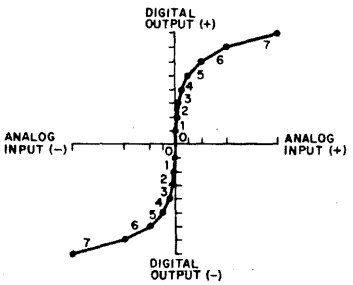
Companding or signal compression and signal expansion is widely used. In FM broadcasting companding is performed by de-emphasis and pre-emphasis. In analog systems companding is performed by log and antilog amplifiers. But in data conversion and transmission, companding has been limited to the telecommunications industry. They recognized the need to efficiently represent analog signals with the fewest possible number of digital bits. With just 8 bits, the standard format of microprocessors, RAM's, ROM's and registers, telecommunications companding systems achieve very low signal-to-quantizing distortion over a 40dB range of speech amplitudes by using the Bell System μ-255 logarithmic companding law.

BELL μ-255 LOGARITHMIC CHARACTERISTIC

The output of the DAC-76 is an approximation to the μ-255 law which can be expressed as:

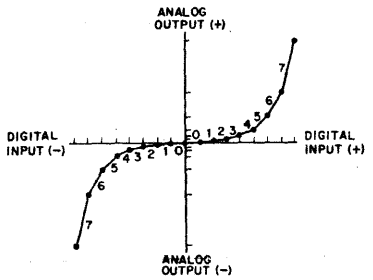
$Y = 0.18 \ln (1 + \mu x)$ where:

X = Normalized input signal level of the compressor (encoder), V_{IN}/V_{FS} with values from −1 to +1.



Y = Output signal level of the encoder

μ = 255



This law is implemented by the DAC-76 with an eight chord (or segment) piecewise linear approximation for each polarity with sixteen linear steps in each chord. A dynamic range of 72dB in both polarities is achieved with 8 bit coding.

TRANSFER CHARACTERISTICS

ENCODE TRANSFER CHARACTERISTIC (A/D CONVERSION)

DECODE TRANSFER CHARACTERISTIC (D/A CONVERSION)

The system transfer characteristics above result when the DAC-76 is used for signal compression (A/D conversion) and for signal expansion (D/A conversion). As one would expect, when the curves are superimposed their average is a straight line because compression and expansion must be equal and opposite.

Both transfer characteristics show outputs divided into 8 chords in both polarities with 16 equal steps in each chord. Note that each chord endpoint is approximately 6dB down from the next higher chord's endpoint and that the chord slopes are binarily-related.

The table below relates step size in each chord to other commonly-encountered measurements and to the equivalent, conventional, binary-coded DAC. Step size (except in Chord 0) is about 0.3dB and is an almost constant percentage of reading. In addition, there is a 1 1/2 step change between the maximum code in each chord and the minimum code in the next chord to smooth the chord transitions and to conform with existing telecommunication specifications.

The following three pages contain electrical specifications, the DC test circuit, tables of ideal chord endpoint currents for both encode and decode modes, and parameter definitions.

STEP SIZE SUMMARY TABLE DECODE OUTPUT (SIGN BIT EXCLUDED)

SPECIFICATION PARAMETER DEFINITIONS

STEP NONLINEARITY: Step size deviation from ideal within a chord.

ENCODE CURRENT: The difference between I_{OE}(+) and I_{OD}(+) or the difference between I_{OE}(–) and I_{OD}(–) at any code.

FULL SCALE DRIFT: The change in output current over the full operating temperature with V_{REF} = 10.000V, R11 = 18.94KΩ, and R12 = 20KΩ.

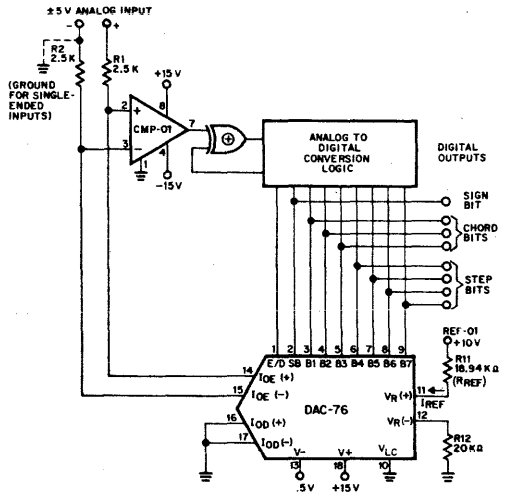
FULL SCALE SYMMETRY ERROR: The difference between I_{OD}(–) and I_{OD}(+) or the difference between I_{OE}(–) and I_{OE}(+) at full scale output.

OUTPUT VOLTAGE COMPLIANCE: The maximum output voltage swing at any current level which causes <1/2 step change in output current.

CHORDS: Groups of linearly-related steps in the transfer function. Also known as segments.

CHORD ENDPOINTS: The maximum code in each chord. Used to specify accuracy.

STEPS: Increments in each chord which divide it into 16 equal levels.



OUTPUT LEVEL NOTATION: Each output current level may be designated by the code $I_{C,S}$ where C = chord number and S = step number. For example, $I_{0,0}$ = zero scale current; $I_{0,1}$ = first step from zero; $I_{0,15}$ = endpoint of first chord (C_0); $I_{7,15}$ = full scale current.

DYNAMIC RANGE: Ratio of the largest output ($I_{7,15}$) to the smallest output excluding zero ($I_{0,1}$) expressed in dB. This can be measured peak or peak-to-peak with the same result.

BASIC ENCODE OPERATION (COMPRESSING A/D CONVERSION)

BASIC ENCODE CONNECTIONS

ENCODE TRANSFER CHARACTERISTIC (A/D CONVERSION)

ENCODE DECISION LEVELS

Compressing A/D conversion with the DAC-76 requires a comparator, an exclusive-or gate, and a successive approximation register—the usual elements in any sign-plus-magnitude A/D converter. However, a compressing ADC has one significant difference from regular A/D converters.

In a conventional (linear) converter, the step size is a constant percentage of full scale, but in a compressing A/D converter, the step size increases as the output changes from zero scale to full scale. The standard 1/2 step bias used in conventional ADC's to keep quantizing error below ±1/2 step cannot be easily furnished by the user of a compressing ADC. For this reason, the DAC has a 1/2 step greater output in the encode mode than it has in the decode mode. This may be seen clearly by comparing the normalized encode and decode output tables at any code point.

ENCODING SEQUENCE

An encoding sequence begins with the Sign Bit comparison and decision. During this time the comparator is a polarity detector only. The Encode/Decode (E/D) input is held at a logic "0". Therefore, no current flows into the encode outputs, and the comparator is effectively disconnected from the DAC. Once the input polarity has been determined, the E/D input is changed to a logic "1" allowing current to flow into $I_{OE}(+)$ or $I_{OE}(-)$ depending upon the Sign Bit Answer.

For positive inputs, current flows into $I_{OE}(+)$ through R1, and the comparator's output will be entered as the answer for each successive decision. For negative inputs, current flows into $I_{OE}(-)$ through R2 developing a negative voltage which is compared with the analog input. An exclusive-or gate inverts the comparator's output during negative trials to maintain the proper logic coding, all ones for full scale and all zeros for zero scale. (A more complete schematic is shown in the applications section.)

The bits are converted with a successive removal technique, starting with a decision at the code 011 1111 and turning off bits sequentially until all decisions have been made. Successive removal is necessary because the 1/2 step encode decision level current is drawn from the sum node, rather than sourced into it.

NEG FULL SCALE	0	0	1	1	1	1	1	1	1	−5.019V

DECODE OPERATION

D/A conversion with the DAC-76 may be illustrated by using an operational amplifier connected to the decode outputs as a balanced load. The decode mode of operation is selected by applying a logic "0" to the Encode/Decode input. This enables the I_{OD} outputs, disables the I_{OE} outputs, and allows $I_{OD}(+)$ or $I_{OD}(-)$ to be selected by the Sign Bit input. When the Sign Bit input is high, a logic "1", all of the output current flows into $I_{OD}(+)$ forcing a positive voltage at the operational amplifier's output. When the Sign Bit input is low, a logic "0", all of the output current flows into $I_{OD}(-)$ through R2 forcing a negative voltage output. Since the Sign Bit only steers current into $I_{OD}(+)$ or $I_{OD}(-)$, the output will always be symmetrical, limited only by the matching of R1 and R2.

NORMALIZED TABLES

The encode and decode tables may be used to calculate ideal output current at any code point. For example, in decode mode at $I_{3,7}$ (011 0111) find 343. 343/8031 times I_{FS} of 2007.75μA equals 85.75μA. Alternatively, use the condensed current tables and add up the number of steps.

BASIC REFERENCE CONSIDERATIONS

Full scale output current is ideally 2007.75μA when the reference current is 528μA in the decode mode. In the encode mode it is 2039.75μA because the additional 1/2 step adds 32μA to the output. A percentage change in I_{REF} caused by changes in V_{REF} or R_{REF} will produce the same percentage change in output current.

The large step size at full scale allows the use of inexpensive references in many applications. In some situations V_{REF} may even be the positive power supply. For example, with V+ = 15V, R_{REF} = 15V/528μA or 28.4KΩ. When using a power supply as a reference, R11 should be two resistors, R11A and R11B, and the junction should be bypassed to ground to provide decoupling.

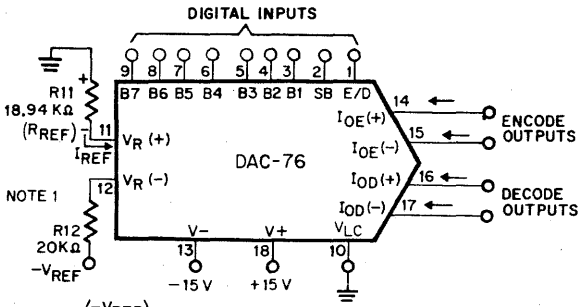
REFERENCE AMPLIFIER OPERATION

POSITIVE REFERENCE OPERATION



$I_{REF} = \frac{V_{REF}}{R_{REF}}$

DECODE OUTPUTS IDEAL VALUES:
$I_{REF} = 528\mu A$
$I_{FS} = 2007.75\mu A$

ENCODE OUTPUTS IDEAL VALUES:
$I_{REF} = 528\mu A$
$I_{FS} = 2039.75\mu A$

NOTE 1: RECOMMENDED WHEN V_{REF} IS V+ OR THE LOGIC POWER SUPPLY.
NOTE 2: PINS 11 AND 12 ARE EQUAL IN VOLTAGE. V_{REF} IS IMPRESSED ACROSS R11 (R_{REF})

NEGATIVE REFERENCE OPERATION

$I_{REF} = -\left(\frac{-V_{REF}}{R_{REF}}\right)$

DECODE OUTPUTS IDEAL VALUES:
$I_{REF} = 528\mu A$
$I_{FS} = 2007.75\mu A$

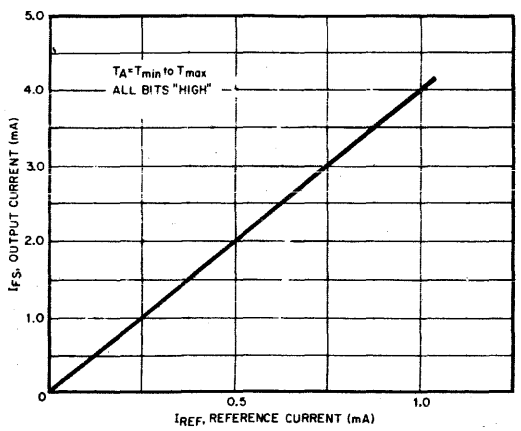
ENCODE OUTPUTS IDEAL VALUES:
$I_{REF} = 528\mu A$
$I_{FS} = 2039.75\mu A$

NOTE 1: PINS 11 AND 12 ARE EQUAL IN VOLTAGE. V_{REF} IS IMPRESSED ACROSS R11 (R_{REF}).

REFERENCE AMPLIFIER SETUP

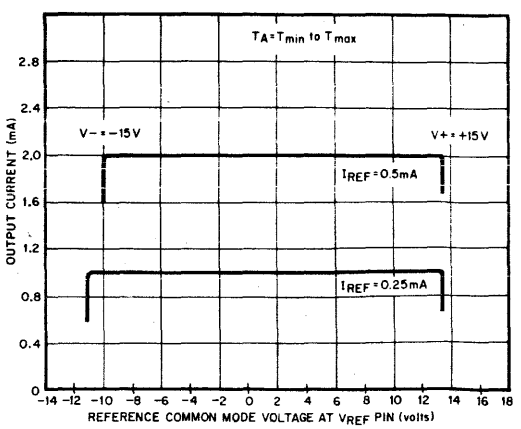
The DAC-76 is a multiplying D/A converter in which the output current is the product of the normalized digital input and the input reference current. The reference current may be fixed or may vary from nearly zero to +1.0mA. The full scale output current is a linear function of the reference current and is given for all four outputs in the figures above.

In positive reference applications an external positive reference voltage forces current through R11 into the $V_R(+)$ terminal (pin 11) of the reference amplifier. Alternatively, a negative reference may be applied to $V_R(-)$ at pin 12; reference current flows from ground through R11 into $V_R(+)$, as in the positive reference case. This negative reference connection has the advantage of a very high impedance presented at pin 12. The voltage at pin 11 is equal to and tracks the voltage at pin 12 due to the high gain of the internal reference amplifier. R12 (nominally equal to R11) is used to cancel bias current errors and may be eliminated with only a minor increase in error.



REFERENCE RECOMMENDATIONS

For most applications a +10.0V reference, such as the PMI REF-01, is recommended for optimum full scale temperature coefficient performance. (This also minimizes the contributions of reference amplifier V_{OS} and TCV_{OS}.) For most applications the tight relationship between I_{REF} and I_{FS} eliminates the need for trimming I_{REF}; but if desired, full scale trimming may be accomplished by selecting R11 or by using a potentiometer for R11.



Using lower values of reference current reduces negative power supply current and increases reference amplifier negative common mode range. While the recommended operating range of DC reference currents is 0.1mA to 1.0mA, monotonic operation is maintained over an even wider range allowing the DAC-76 to be used in many multiplying applications. For variable reference applications, see section entitled "Multiplying Operation."

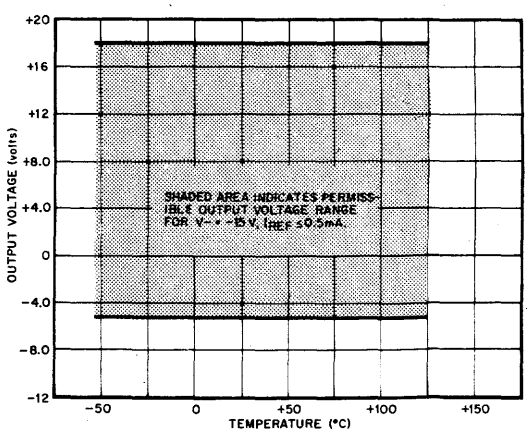
NOTE: THE SUM OF THE COMMON MODE VOLTAGE AND THE DIFFERENTIAL VOLTAGE ACROSS THE LOAD SHOULD BE WITHIN THE −5V TO +18V OUTPUT VOLTAGE COMPLIANCE SPECIFICATION.

The DAC-76 has true current outputs with wide voltage compliance enabling fast drive of a variety of single-ended and balanced loads. Positive voltage compliance is +18V, and negative voltage compliance is −5.0V with I_{REF} = 528μA and V− = −15V. Negative voltage compliance for other values of I_{REF} and V− may be calculated using the table above. Typical connections, both single-ended and differential, are shown in the figure above with output voltage tables. Note the differential sign-plus-magnitude relationship between "B" and "C". The differential output voltage is independent of the +5.00 nominal voltage source as long as the $V_{OC}(-)$ minimum values are observed.



High common mode output range is possible due to the wide output voltage compliance and allows use with transformers or other balanced loads. The terminating impedances may be located a distance away from the DAC-76 allowing transmission of analog quantities as currents rather than voltages and elimination of ground loop errors. Capacitive termination is also possible, performing an "integrate-and-hold" process which is a function of V_{REF}, R_{REF}, the digital input code, and the selection time for a given current output. Resetting of the integrating capacitor may be accomplished with a CMOS switch in parallel with the capacitor. Thus, many applications traditionally requiring op amps may be performed with a high voltage compliance, current output DAC.

LOGIC INPUT AND POWER SUPPLY CONSIDERATIONS

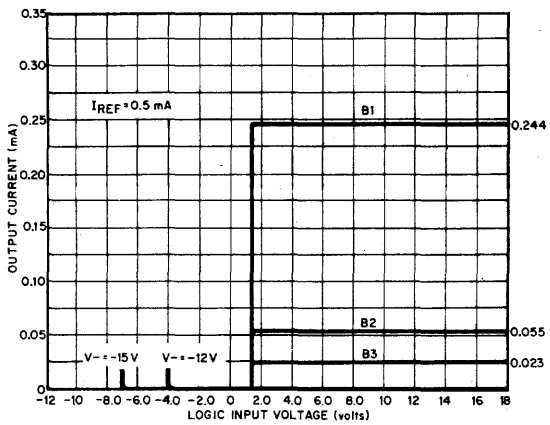
INTERFACING CIRCUIT FOR ECL, CMOS, HTL, & NMOS LOGIC INPUTS

NOTE 1: SET THE VOLTAGE "A" TO BE AT THE DESIRED LOGIC INPUT SWITCHING THRESHOLD.
NOTE 2: ALLOWABLE RANGE OF LOGIC THRESHOLD IS TYPICALLY -5V TO +13.5V WHEN OPERATING THE DAC-76 ON ±15V SUPPLIES.

LOGIC INPUTS

The DAC-76 may be interfaced with other-than-TTL logic by placing V_{LC} (pin 10) at a potential which is 1.4V below the desired logic input switching threshold. However, this voltage source must be capable of sourcing and sinking a changing current at pin 10.

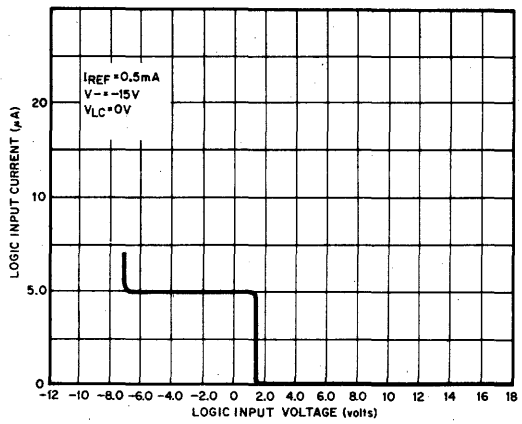
The negative voltage at the logic inputs must be limited to +10V with respect to V– (pin 13).



POWER SUPPLIES

As shown in the curves below, power supply current drain is relatively independent of voltage and temperature and completely independent of the logic input states.

When operating with V– between –15V and –11V, output negative voltage compliance, $V_{OC}(-)$, reference input amplifier common mode voltage range, and logic input negative voltage range are reduced by an amount equivalent to the difference between –15V and the V– supply in use. Operation with V+ between +5V and +15V affects V_{LC} and the reference amplifier common mode positive voltage range in the same manner.



TYPICAL PERFORMANCE CURVES

2. $\overline{\text{START}}$ MUST BE HELD LOW FOR ONE CLOCK CYCLE TO BEGIN A SEND OR RECEIVE CYCLE.
3. THE SAR IS USED AS A SERIAL-IN/PARALLEL OUT REGISTER IN THE RECEIVE MODE.
4. CLOCK AND $\overline{\text{START}}$ MAY BE CONNECTED IN PARALLEL AT BOTH ENDS.
5. CONVERSION IS COMPLETED IN 9 CLOCK CYCLES.
6. RECEIVE OUTPUT IS AVAILABLE FOR ONE FULL CLOCK CYCLE

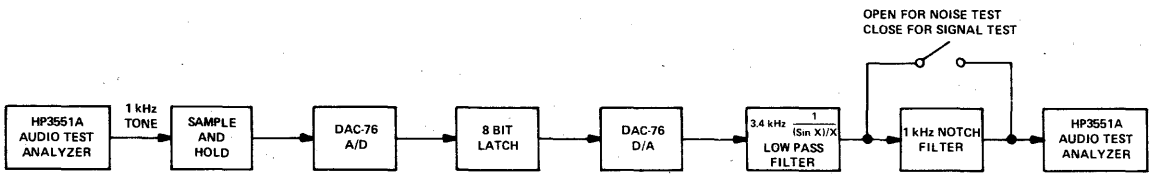
TYPICAL SIGNAL TO QUANTIZING DISTORTION CURVES

SIGNAL TO QUANTIZING DISTORTION VS. INPUT LEVEL (3 kHz FLAT FILTER)

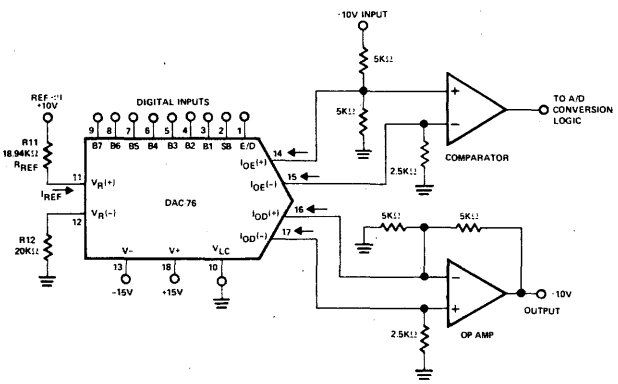
NOTE: 0dB IS ±3.5V. +3dB IS ±5.0V OR FULL SCALE CODE (111 1111).



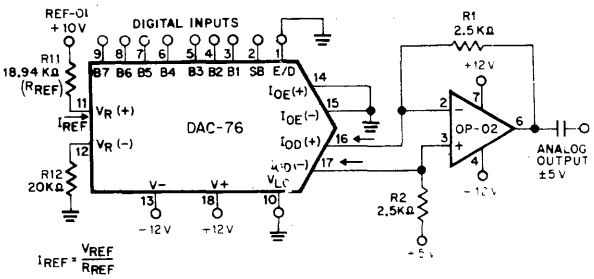
SIGNAL TO QUANTIZING DISTORTION VS. INPUT LEVEL (C-MESSAGE WEIGHTING FILTER & BELL SPEC)

NOTES:
1. 0dB IS ±3.5V. +3dB IS ±5.0V OR FULL SCALE CODE (111 1111).
2. C-MESSAGE WEIGHTING FILTER PROVIDES A FREQUENCY RESPONSE CHARACTERISTIC WHICH SIMULATES THE PERCEIVED RESPONSE OF THE HUMAN EAR TO TELEPHONE NOISE.

Note: Quantizing distortion is the difference between the original signal and the processed signal (i.e., after encoding and decoding).



SIGNAL TO QUANTIZING DISTORTION TEST CIRCUIT BLOCK DIAGRAM

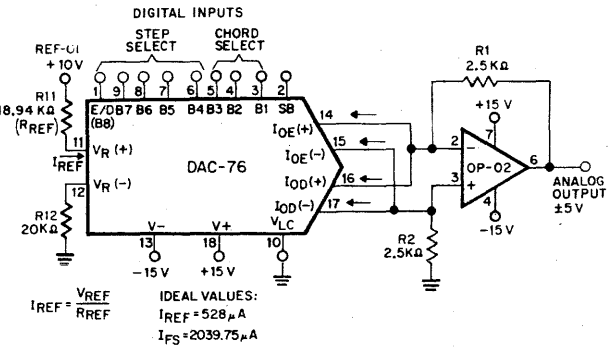


1. 8 kHz SAMPLING CONDITIONS: 62.5μsec SAMPLE PERIOD, 62.5μsec A/D CONVERSION TIME.
2. AUDIO TEST ANALYZER CONTAINS A C-MESSAGE FILTER AND A 3 kHz FLAT FILTER.

OUTPUT COMPLIANCE EXTENSION CONNECTIONS

±10V RANGE ENCODE/DECODE CONNECTIONS

COMPLIANCE EXTENSION USING AC COUPLED OUTPUT



$I_{REF} = \frac{V_{REF}}{R_{REF}}$

IDEAL VALUES:
$I_{REF} = 528\mu A$
$I_{FS} = 2007.75\mu A$

EXTENSION TO SIGN PLUS 78dB DYNAMIC RANGE

EXTENDED RANGE CONNECTIONS

EXTENDED RANGE OPERATION

When used as a D/A converter only, the DAC-76 range may be extended from sign + 72dB to sign + 78dB by using the encode output current to insert additional levels halfway between each step. By connecting $I_{OD}(+)$ to $I_{OE}(+)$ and $I_{OD}(-)$ to $I_{OE}(-)$, the E/D logic input functions as a fifth step bit input. Full scale positive now becomes 1 111 11111; full scale negative is 0 111 11111. Each chord is divided into 32 steps instead of the former 16 steps, effectively increasing dynamic range by 6dB.

The accompanying table summarizes the new chord and step characteristics obtained in the extended connection shown above.

SUMMARY TABLE FOR 3 CHORD BITS AND 5 STEP BITS

CHORD	STEP (μA)	RANGE (μA)	STEP (mV)	RANGE (V)
0	0.25	0 to 7.75	0.625	0 to 0.019
1	0.5	8.25 to 23.75	1.25	0.021 to 0.059
2	1.0	24.75 to 55.75	2.5	0.062 to 0.139
3	2.0	57.75 to 119.75	5.0	0.144 to 0.299
4	4.0	123.75 to 247.75	10	0.309 to 0.619
5	8.0	255.75 to 503.75	20	0.639 to 1.259

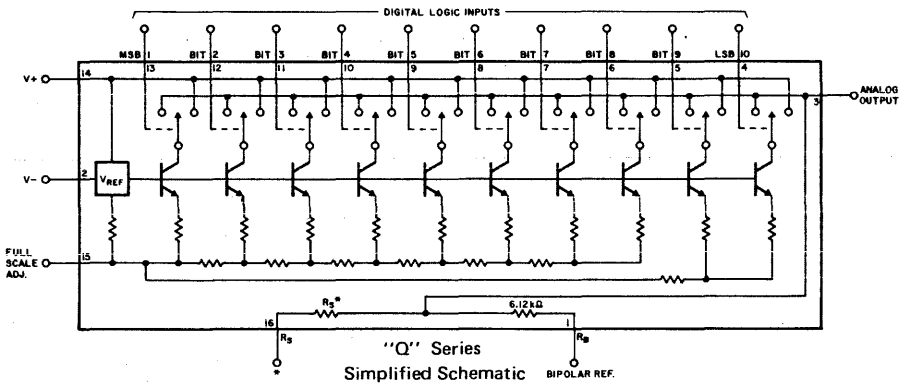
DAC-100

8 & 10 BIT DIGITAL-TO-ANALOG CONVERTER

GENERAL DESCRIPTION

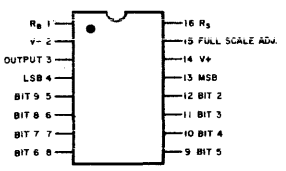
The DAC-100 is a complete 10 bit resolution Digital-to-Analog converter constructed on two monolithic chips in a single 16-pin DIP or 24-pin flatpack. Featuring excellent non-linearity vs. temperature performance, the DAC-100 includes a low tempco voltage reference, 10 current source/switches and a high stability thin-film R-2R ladder network. Maximum application flexibility is provided by the fast current output and by matched bipolar offset and feedback resistors which are included for use with an external op amp for voltage output applications. Although all units have 10-bit resolution, a wide choice of nonlinearity and tempco options is provided to allow price/performance optimization.



The small size, wide operating temperature range, low power consumption and high reliability construction make the DAC-100 ideal for aerospace applications. Other applications include use in servo-positioning systems, X-Y plotters, CRT displays, programmable power supplies, analog meter movement drivers, waveform generators and high speed Analog-to-Digital converters.

FEATURES

- **Complete . . . . . Internal Reference**
- **Flexible . . . . . 0 to 2mA Output**
- **Fast Settling . . . . 225nsec (8 Bits), 375nsec (10 Bits)**
- **Stable . . . . . Tempcos to ±15ppm/°C Max**
- **0°C/+70°C, −25°C/+85°C, −55°C/+125°C Models Available**
- **TTL and DTL Compatible Logic Inputs**
- **Wide Supply Range . . . . . ±6V to ±18V**
- **8 and 10 Bit Versions Available**
- **MIL-STD-883A Class B Processing Models Available**
- **Low Cost Q3, Q4 Series**



SIMPLIFIED SCHEMATIC AND PIN CONNECTIONS — 16 LEAD HERMETIC DIP

*For 10V or ±5V Operation
R_S = 4.88kΩ (Package Q1, Q3, Q5)
For 5V or ±2.5V Operation,
R_S = 2.44kΩ (Package Q2, Q4 or Q6)

GENERAL INFORMATION

1. The DAC-100 series are digital-to-analog current converters; voltage outputs are implemented by using an external operational amplifier with the internally-provided feedback resistor. For clarity and convenience, most specifications will reference full scale output voltage rather than full scale output current, assuming an "ideal" op amp has been utilized for conversion (See test circuit at right).

2. The logic coding used for driving the DAC-100 should be complementary binary or offset complementary binary to obtain unipolar and bipolar analog outputs, respectively.

3. As shown in the ordering information below, the DAC-100 series provides a wide variety of worst-case nonlinearity and full-scale tempco combination options. All devices have 10 bits of resolution; the nonlinearity options of ±0.05%, ±0.1%, ±0.2% and ±0.3% guarantee monotonic operation for resolutions of 10, 9, 8, and 7 bits respectively. When less than the full 10 bits are utilized, the unused logic inputs must be connected to a "high" logic level (>2.1 V).

FULL SCALE TEST CIRCUIT

DEFINITION: Full Scale Tempco is defined as the change in output voltage measured in the circuit above and is expressed in ppm between 25°C and either temperature extreme divided by the corresponding temperature change.

NOTE: Since R_S precisely tracks the internal R-2R ladder network over temperature, the absolute I_{FS} Tempco of ±120ppm/°C is cancelled by R_S when the output voltage is used as in the above circuit

ORDERING INFORMATION

ORDER NUMBER: DAC-100 X X X X

NONLINEARITY		F.S. TEMPCO		PACKAGE		TEMP RANGE AND OUTPUT VOLTAGE
A	±0.05% MAX	A	15 ppm/°C MAX	Q	16 Pin HERMETIC DUAL-IN-LINE	as shown below
B	±0.1% MAX*	B	30 ppm/°C MAX*	N	24 Pin HERMETIC FLATPACK	
C	±0.2% MAX	C	60 ppm/°C MAX			
D	±0.3% MAX	D	120 ppm/°C MAX			

*NOTE: For DAC-100 BBQ5 and DAC-100 BBQ6 only; nonlinearity is ±0.1% over -25°C to +85°C and ±0.12% over -55°C to +125°C. Full Scale Tempco is 30 ppm/°C over -25°C to +85°C and 40 ppm/°C over -55°C to +125°C.

INTERFACING WITH CMOS LOGIC

The DAC-100 requires only about 1μA of input current into each logic stage. This enables use with CMOS inputs as long as one rule is observed: logic input voltages should not exceed 6.5 volts or V+, whichever is smaller. To provide an understanding of this rule, it is necessary to discuss the logic input stage design.

LOGIC INPUT STAGE DESIGN

For simplicity, only one of the ten identical input circuits is shown below. The DAC-100 uses a fast current-steering technique that switches a bit-weighted current between the positive supply (V+) and the analog output, which is usually constrained to be at zero volts (virtual ground) by an external summing amplifier.

Switching is accomplished by forward biasing Q4, a diode-connected transistor, for the bit "on" condition and back biasing Q4 in the "off" condition. For the "on" condition ($V_{IN} \leqslant .7$ volts), Q3 is "off"—all of the bit-weighted current, I_1, flows from the analog output through Q4 and ultimately to V-. In the "off" condition ($V_{IN} \geqslant 2.1$ volts), Q3 is "on", Q4 is back biased, and the bit-weighted current is sourced from the positive power supply instead of the analog output.

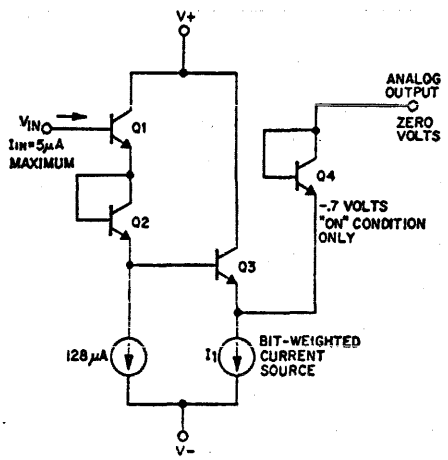
If V_{IN} is too high, Q4's emitter-base junction will experience reverse breakdown and a fault condition will occur. Equation 1 describes this condition:

$$1)\ BV_{IH} = V_{BE1} + V_{BE2} + V_{BE3} + BV_{EB4} \cong 7.7 \text{ volts}$$

Using this relationship, it can be seen that a conservative input voltage limit would be around 6.5 volts. When the 6.5V input limit is observed, DAC-100 operation with CMOS inputs is easily achieved.

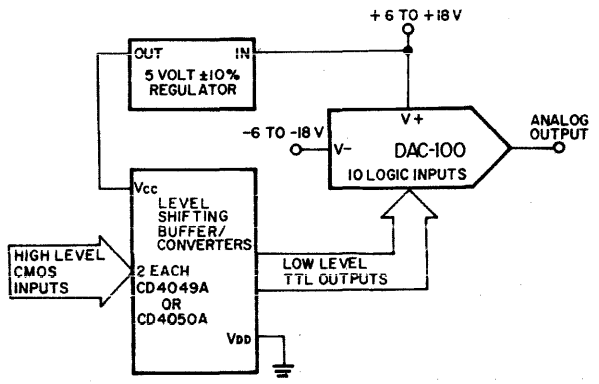
±6 VOLT POWER SUPPLY OPERATION

This is the most convenient method of interfacing the DAC-100 with CMOS logic. At ±6 volts, DAC-100 power dissipation is only 80mW, which is very small considering the inclusion of a complete internal reference. No interfacing components are required with ±5% power supplies, and the CMOS logic and DAC-100 can use the same +6 volt power supply. In this application the device is directly CMOS compatible.



HIGH LEVEL CMOS INTERFACING

The block diagram below illustrates a convenient method for interfacing CMOS input levels between 6.5 volts and 15 volts with DAC-100. Inexpensive and readily available CMOS hex buffer/converters step down the high-level inputs to TTL levels that cannot exceed 5 volts—clearly satisfying the input stage voltage rule.



In addition to level shifting, buffer/converters provide input coding flexibility since they are available as inverting (CD4049A) or noninverting (CD4050A) devices. This gives the user a choice between negative-true and positive-true binary coding and allows the same basic DAC-100-to-CMOS interfacing method to be used in either type of application.

Since buffer/converter power consumption is very low, the required +5 volts can be provided by a simple regulator or even a resistive divider in some applications. In a multi-DAC system, one central, inexpensive 3-terminal IC regulator can supply several level shifting devices.

NOTE: For a more complete explanation and detailed circuit connections, refer to AN-14, "Interfacing PMI D/A's with CMOS Logic."

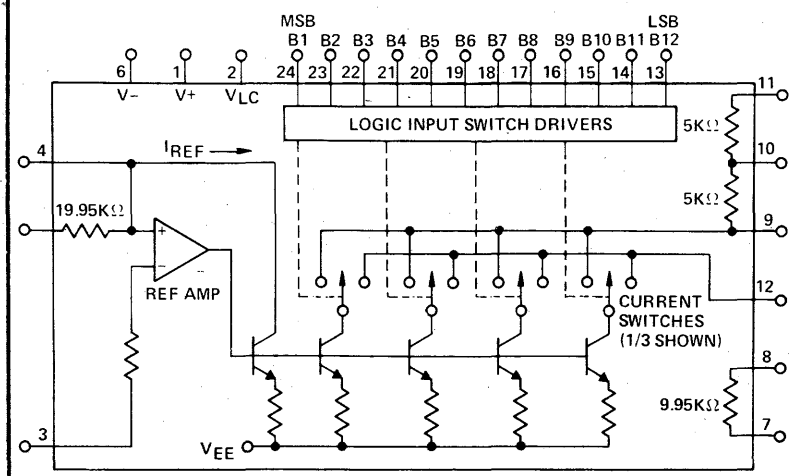
12 BIT MULTIPLYING D/A CONVERTER

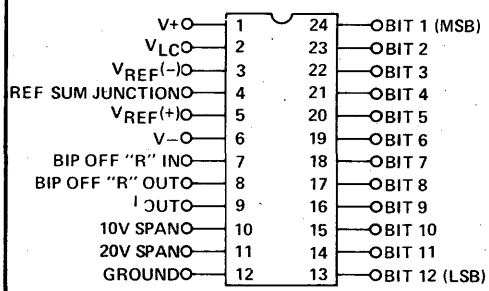
GENERAL DESCRIPTION

The SSS562 is a 12-bit monolithic multiplying Digital-to-Analog converter consisting of a reference current amplifier, an R-2R ladder network, range and offset scaling resistors, and 12 high speed current switches. Improvements over the AD562 include faster settling time, lower power dissipation, greater negative power supply range, and wider voltage compliance. The SSS562 is directly interchangeable with the AD562.



The SSS562 uses a unique trimming method, selective shorting of zener diodes by avalanche migration, to achieve 13 bit accuracy rather than laser trimming. Reliability of this trimming method has been proven in several other PMI products with over 3 years of reliability history. The SSS562 is recommended for 12 bit accuracy D/A applications where single chip reliability, small size and low cost are primary considerations.

FEATURES



- Single Chip Monolithic Construction*
- Binary and BCD Models
- Nonlinearity to ±1/4 LSB (Max)
- Improved Settling Time . . . . . 1.5 μsec (Max)
- Fits AD562 Socket Directly
- Guaranteed Monotonicity
- High Speed Multiplying Capability
- TTL and CMOS Logic Input Compatibility
- Low Power Consumption
- Low Cost
- MIL-STD-883A Level B Models Available

For improved specifications and greater applications flexibility, see the DAC-12 High Speed Multiplying D/A Converter data sheet.

MULTIPLYING ELECTRICAL CHARACTERISTICS AT T_A = +25°C (ALL MODELS)

Parameter	Description	Typ	Units
Quadrants	Two-quadrant: bipolar operation is achieved using the digital inputs only.	–	–
Reference Voltage	Unipolar. Digital input multiplies reference voltage.	0 to +10	V
Accuracy	10 bits for reduced reference voltage of +1V.	±0.05	%FS
Reference Feedthrough (Unipolar Mode)	All bits OFF, 0 to +10V (p-p) sinewave frequency for 1/2 LSB (p-p) feedthrough.	2.0	KHz
Output Slew Rate	All bits ON, 10V step change in reference voltage.	1.0	mA/μsec
Output Settling Time	All bits ON, 10V step change in reference voltage, to ±0.01% FS.	5.0	μsec
Reference Amplifier Bandwidth	Closed loop, small signal.	1.0	MHz

ADJUSTMENT PROCEDURES AND TABLE

BIPOLAR OFFSET

With all bits OFF, adjust R1 until op amp output is –2.5V on ±2.5V range, –5.0V on ±5.0V range, or –10.0V on ±10.0V range.

UNIPOLAR OFFSET

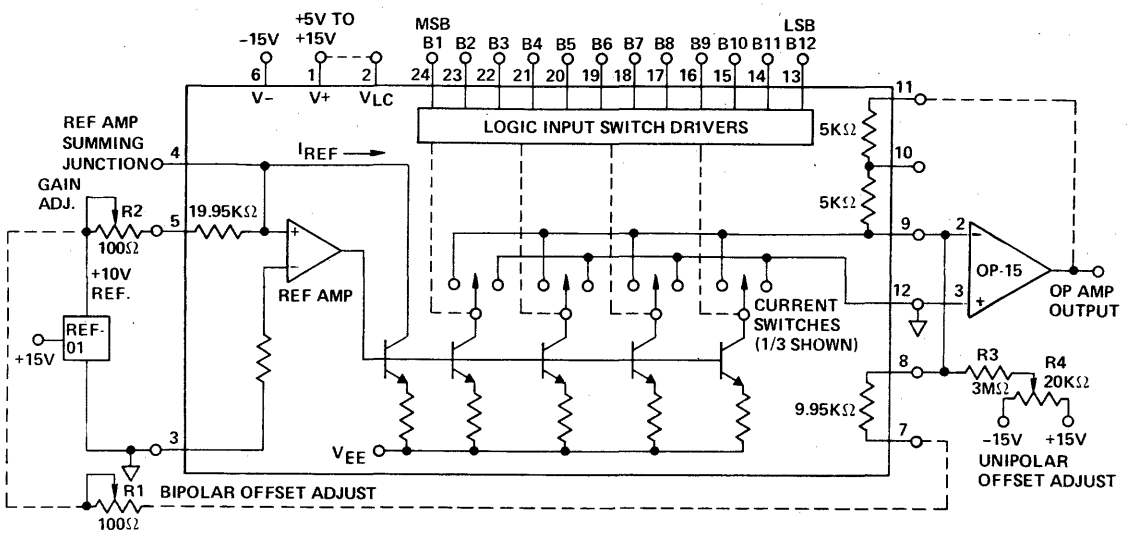
With all bits OFF, adjust R4 until op amp output is 0V. R1 and the connection from pin 8 to pin 9 are not required.

BIPOLAR BCD GAIN

Turn bits 2 and 4 ON, Turn bits 1, 3, 5 through 12 OFF. Adjust R2 until op amp output is 0V.

BIPOLAR BINARY GAIN

Turn bit 1 (MSB) ON. Turn bits 2 through 12 OFF. Adjust R2 until output is 0V.



UNIPOLAR BCD GAIN

Turn bits 1, 4, 5, 8, 9, 12 ON (Code 1001 1001 1001, BCD 999). Adjust R2 until op amp output is +4.995V for 0 to +5.0V range, or +9.990V for 0 to +10.0V range.

UNIPOLAR BINARY GAIN

Turn all bits ON. Adjust R2 until op amp output is +4.9988V for 0 to +5.0V range, or +9.9976V for 0 to +10.0V range.

RANGE	OP AMP	CONNECTIONS	OFFSET ADJUST
–2.5V to +2.5V	Out to Pin 10	Pin 11 to Pin 9	R1 as below
–5.0V to +5.0V	Out to Pin 10	N.C. to Pin 11	R1 as below
–10.0V to +10.0V	Out to Pin 11	N.C. to Pin 10	R1 as below
0 to +5.0V	Out to Pin 10	Pin 11 to Pin 9	R4 as below
0 to +10.0V	Out to Pin 10	N.C. to Pin 11	R4 as below

NOTES: 1. FOR TTL AND DTL INPUTS, CONNECT +5V TO PIN 1; PIN 2 MAY BE GROUNDED OR LEFT OPEN.
2. FOR LOW VOLTAGE CMOS, CONNECT +5V TO PIN 1; SHORT PIN 2 TO PIN 1.
3. FOR HIGH VOLTAGE CMOS, CONNECT +15V TO PIN 1; SHORT PIN 2 TO PIN 1.

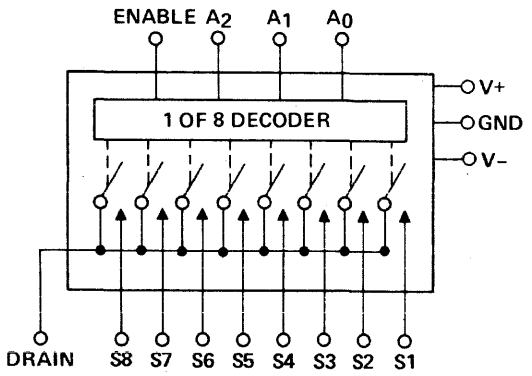
MUX-08

PROTECTED 8 CHANNEL BI-FET ANALOG MULTIPLEXER

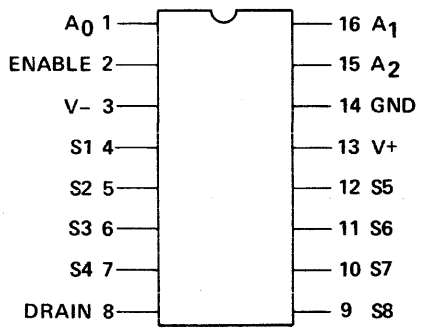
GENERAL DESCRIPTION



The MUX-08 is a monolithic 8 channel analog multiplexer which connects a single output to 1 of the 8 analog inputs depending upon the state of a 3-bit binary address. Disconnection of the output is provided by a logical "0" at the ENABLE input, thereby providing a package select function.

Fabricated with Precision Monolithics' high performance BI-FET technology, this device features overvoltage protection that is fail safe with power loss, while offering low, constant "ON" resistance. Performance advantages include low leakage currents and fast settling time with low crosstalk to satisfy a wide variety of applications. This multiplexer does not suffer from latch-up or static charge blow-out problems associated with similar CMOS parts. The digital inputs are designed to operate from both TTL and CMOS levels while always providing a definite break-before-make action without the need for external pullup resistors.

FEATURES



- Pin Compatible With DG508, HI-508A, LF11508
- JFET Switches Rather Than CMOS
- No Static Discharge Blow-out Problem
- No SCR Latch-up Problems
- Analog Inputs Overvoltage Protected ±20V Beyond Normal Ratings
- Fail Safe With Power Loss
- Low "ON" Resistance . . . . . 220Ω TYP
- Low Output Leakage Current . . . . . 100nA MAX
- Digital Inputs Compatible With TTL and CMOS
- No Pullup Resistors Required To Insure Break-Before-Make Action With TTL Inputs

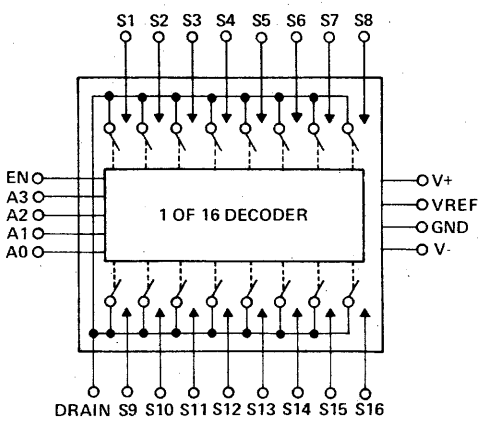
MUX-16

PROTECTED 16 CHANNEL BI-FET ANALOG MULTIPLEXER

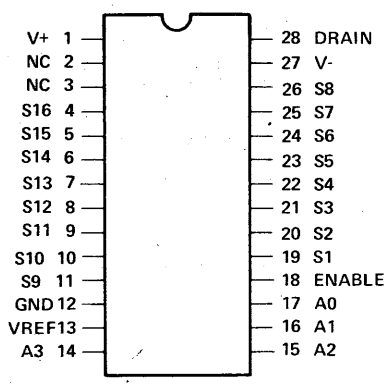
GENERAL DESCRIPTION



The MUX-16 is a monolithic 16 channel analog multiplexer which connects a single output to 1 of the 16 analog inputs depending upon the state of a 4-bit binary address. Disconnection of the output is provided by a logical "0" at the ENABLE input, thereby providing a package select function.

Fabricated with Precision Monolithics' high performance BI-FET technology, this device features overvoltage protection that is fail safe with power loss, while offering low, constant "ON" resistance. Performance advantages include low leakage currents and fast settling time with low crosstalk to satisfy a wide variety of applications. This multiplexer does not suffer from latch-up or static charge blow-out problems associated with similar CMOS parts. The digital inputs are designed to operate from both TTL and CMOS levels while always providing a definite break-before-make action without the need for external pullup resistors.

FEATURES



- Pin Compatible With DG506, HI-506A
- JFET Switches Rather Than CMOS
- No Static Discharge Blow-out Problem
- No SCR Latch-up Problems
- Analog Inputs Overvoltage Protected ±20V Beyond Normal Ratings
- Fail Safe With Power Loss
- Low "ON" Resistance . . . . . 250 Ω TYP
- Digital Inputs Compatible With TTL and CMOS
- No Pullup Resistors Required To Insure Break-Before-Make Action With TTL Inputs

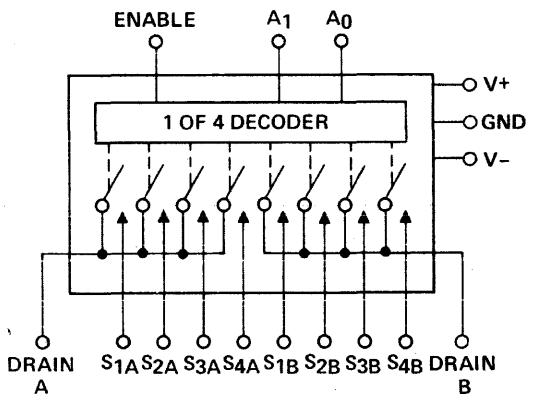
MUX-24

PROTECTED DUAL 4 CHANNEL ANALOG MULTIPLEXER

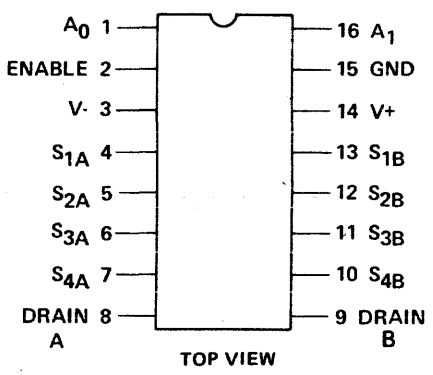
GENERAL DESCRIPTION



The MUX-24 is a monolithic 4-channel differential analog multiplexer configured in a double pole, 4-position (plus OFF) electronic switch array. A 2-bit binary input address connects a pair of independant analog inputs from each 4-channel input section to the corresponding pairof independant analog output "poles". Disconnection of both outputs is provided by a logical '0' at the ENABLE input, thereby offering a package select function.

Fabricated with Precision Monolithics' high performance BI-FET technology, this device features overvoltage protection that is fail safe with power loss, while offering low, constant "ON" resistance. Performance advantages include low leakage currents and fast settling time with low crosstalk to satisfy a wide variety of applications. This multiplexer does not suffer from latch-up or static charge blow-out problems associated with similar CMOS parts. The digital inputs are designed to operate from both TTL and CMOS levels while always providing a definite break-before-make action without the need for external pullup resistors.

FEATURES



- Pin Compatible With DG509, HI-509A, LF11509
- JFET Switches Rather Than CMOS
- No Static Discharge Blow-out Problem
- No SCR Latch-up Problems
- Analog Inputs Overvoltage Protected ±20V Beyond Normal Ratings
- Fail Safe With Power Loss

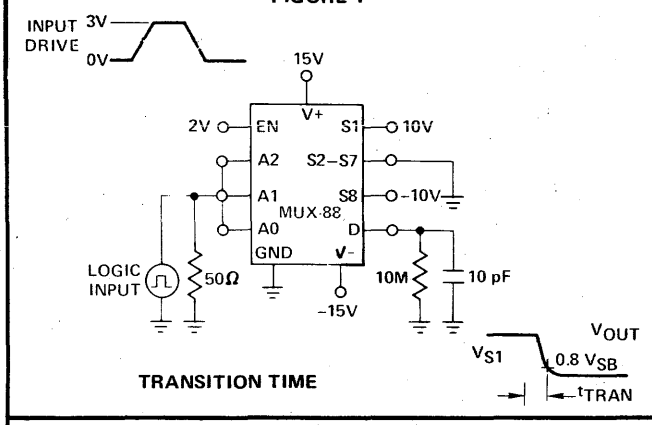
ELECTRICAL CHARACTERISTICS NOTES

NOTE 1: Conditions applied to leakage tests insure worst case leakages. Exceeding 11V on the analog input may cause an "OFF" channel to turn "ON".

NOTE 2: Lots are sample tested to this parameter. The measurement conditions of FIGURE 1 insure worst case transition time.

NOTE 3: "OFF" isolation is measured with all switches "OFF" and driving a source. Crosstalk is measured with R_L = 1K, C_L = 7pF, V_s = 3V RMS, F = 100 kHz.

ELECTRICAL CHARACTERISTICS



These specifications apply for V+ = 15V, V– = –15V and T_A = 25°C unless otherwise specified.

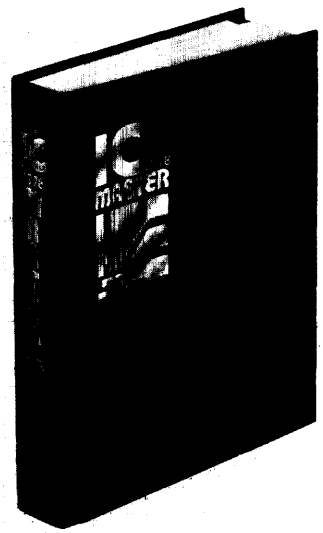
BREAK-BEFORE-MAKE DELAY

FIGURE 4

"ON" RESISTANCE CHARACTERISTICS
$T_A = 25°C$



APPLICATIONS INFORMATION

These analog multiplexers employ ion-implanted JFET's in a switch configuration designed to assure break-before-make action. The turn-off time is much faster than the turn-on time to guarantee this feature over the full operating temperature and input voltage range. Fabricated with BI-FET processing rather than CMOS, special handling is not necessary to prevent damage to this multiplexer. Because the digital inputs only require a 2.0V logic "1" input level, power-consuming pullup resistors are not required for TTL compatibility to insure break-before-make switching as is most often the case with CMOS multiplexers. The digital inputs utilize PNP input transistors where input current is maximum at the logic "0" level and drops to that of a reverse-biased diode (about .1 μA) as the input voltage is raised above $\approx$1.4V.

The "ON" resistance, R_{ON}, of the analog switches is constant over the wide input voltage range of -15V to +11V with $V_{SUPPLY} = \pm 15V$. Input voltages up to $\pm$20V beyond this normal input range are permissible with device power on. Input voltages of up to +11V and lower than -15V are allowable with device power off. Higher input voltage is tolerable provided that some form of current limiting is employed (such as that of an op-amp output stage) to avoid exceeding junction temperature and power dissipation requirements. For normal operation, however, positive input voltages should be restricted to 11V (or 4V less than the positive supply) otherwise leakage currents will increase and a normally "OFF" switch may be falsely turned "ON". Although the output voltage will be erroneous, damage to the multiplexer will not result because the switch "ON" resistance greatly increases and the I_{DSS} of the JFET protects the switch (Figure 4). When operating with negative input voltages, current through an "ON" switch must be externally limited to prevent the voltage drop across the switch from exceeding -0.4V source to drain. This is not a problem generally, for in most applications the multiplexer output will be connected to a high impedance load.

WHEN THE CHIPS ARE DOWN...

THE NEW 1978 IC MASTER PAYS OFF!

The new IC MASTER is the ultimate IC source book.

It lists virtually every IC device manufactured in the United States.

The IC MASTER is the easy, sensible means of narrowing down your IC choices quickly, accurately and systematically. All information is cross-referenced and indexed for rapid problem solving and device selection. And, additionally, the MASTER is updated three times yearly by accumulative supplements.

THE FORMAT OUTLINED:

- **FIVE MASTER SELECTION GUIDES** — Over 85 companies' IC's organized by type, function, key parameters
- **OVER 1500 PAGES OF TECHNICAL INFORMATION** — Provided directly by manufacturers covering 20,000 IC's
- **ALTERNATE SOURCE DIRECTORY** — The only industry-wide, pin-for-pin version available
- **MILITARY PARTS INDEX AND CROSS REFERENCE CHART** — Identifies all IC's with JAN qualification
- **MILITARY DEVICE TESTING TABLE** — List companies that screen to Mil. Std. 883
- **MILITARY PARTS INDEX** — The first functional guide to JAN qualified parts
- **PART NUMBER INDEX** — Parts from over 80 manufacturers, in numerical sequence
- **APPLICATION NOTE DIRECTORY** — Digest of currently active application note material
- **PRODUCT INDEX** — Provides alphanumeric listing of over 80 manufacturers' lines
- **PART NUMBER GUIDE** — Instantly decodes each company's part numbering system
- **MANUFACTURERS AND DISTRIBUTORS DIRECTORY**

DESCRIPTION

The Raytheon 4152 consists of a comparator, a one-shot, a precise gated current-source output, an internal voltage reference, and an open-collector output . . . all on a single monolithic IC chip. These elements can be combined via external pin connections to perform a wide variety of circuit functions.

The versatility of this unique IC makes it easy to tailor the circuit operation to your needs. Pulse width, scale factor, and output drive are set by external resistors as shown in Figure 1. Combine the versatile 4152 with an op amp or two, some digital circuits, and the range of cost-effective applications becomes even greater.

The Raytheon 4152 provides a versatile, low-cost means of accurately converting an analog signal to a pulse train of proportional frequency, and vice versa. It can be imaginatively applied to a broad range of signal conditioning applications once the various functional blocks within the IC are understood.

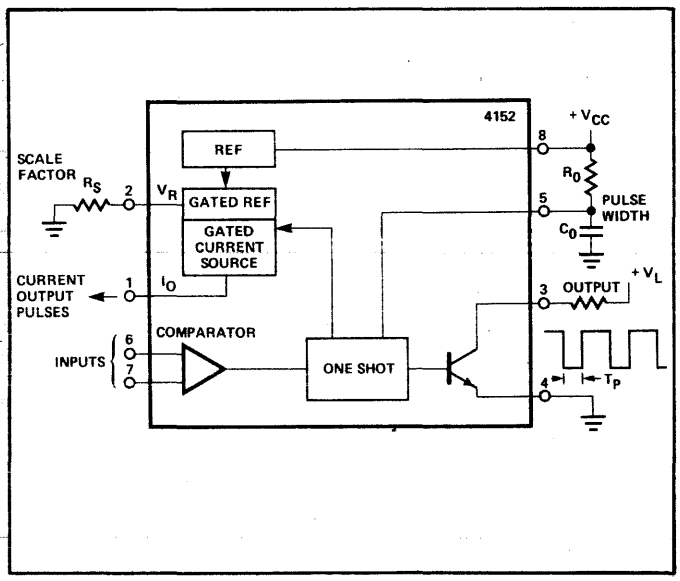

Figure 1. Functional Diagram of Raytheon 4152.

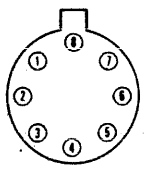
FEATURES



- Single supply operation (+7 V to +22 V)
- Pulse output compatible with all logic forms (DTL/TTL/ CMOS)
- Programmable scale factor (K)
- High linearity ±0.05% max
- Temperature stability ±150 ppm/°C max
- High noise rejection
- Inherent monotonicity
- Easily transmittable output
- Simple full scale trim
- Single-ended input, referenced to ground
- V/F or F/V conversion
- Voltage or current input
- Wide dynamic range

APPLICATIONS

- Precision voltage-to-frequency-converters
- Pulse-width modulators
- Programmable pulse generators
- Frequency-to-voltage converters
- Integrating analog-to-digital converter
- Long-term analog integrator
- Signal conversion —
  - Current-to-frequency
  - Temperature-to-frequency
  - Pressure-to-frequency
  - Capacitance-to-frequency
  - Frequency-to-current
- Signal isolation
  - VFC → opto-isolation → FVC
  - ADC with opto-isolation
- Signal encoding
  - FSK modulation/demodulation
  - Pulse-width modulation
- Frequency scaling
- DC motor speed control

Input Comparator

The input comparator section consists of transistors Q1 through Q7 (see Figure 2). A PNP ground-sensing input stage provides capability of operating down to low input voltages, thus the input range on either input is from zero up to $+V_S$-3V (power supply voltage less three volts). This is particularly important for single-supply operation. Input comparator gain is approximately 10,000. The output of the comparator, transistor Q7, switches from OFF to ON when the input voltage applied to pin 7 becomes more positive than the input voltage on pin 6. The output transistor Q7 going into saturation is used to trigger the one-shot.

One important precaution: The voltage applied to the input comparator (pins 6 and 7) must not be more negative than 0.3 V relative to the ground terminal (pin 4) unless there is protective current limiting. Negative input voltages will saturate the input PNP transistors and cause excessive input base current. This input-base current must not be allowed to exceed 25 mA over an extended period of time or the IC could be damaged. If there is a possibility of continuous excessive negative voltage on the input, then a resistor in series with the input should be added to limit the input current.

One-Shot Circuit

Pulse-width of the one-shot is determined by the external components R_o, C_o that are connected to pin 5. The capacitor C_o is normally discharged through the saturated transistor Q16. When the one-shot timing cycle is initiated, capacitor C_o is released by Q16 turning OFF and allowed to charge towards $+V_{CC}$ through R_o. At 2/3 of $+V_{CC}$, transistor Q16 is switched ON and the capacitor C_o is discharged. The pulse width will therefore be determined by the following equation:

$$1 - \epsilon^{\frac{-T_p}{R_o C_o}} = 0.667$$

$$T_p = 1.1\, R_o C_o$$

Pulse width T_p is independent of supply voltage $+V_{CC}$. For best linearity and stability, R_o and C_o should be selected within a range of 5 KΩ to 500 KΩ and 0.001 μF to 1.0 μF.

A latching action by the RS flip-flop comprised of Q9 and Q11 assures that the timing cycle will be completed regardless of input voltage. The flip-flop is set by Q7 going into the ON state. Q9 is normally OFF and Q11 normally ON; so Q7 going low will cause Q11 to switch OFF and Q9 to switch ON. Since Q9 and Q7 collectors are tied together, Q9 will keep the collectors low regardless of Q7 state. At the end of the timing cycle, Q10 is switched ON and this will make Q9 go OFF. If Q7 is OFF, then the flip-flop can reset to the normal state where Q9 is OFF and Q11 ON. The input state overides this reset action. In FVC applications, it is very important to make the input pulses narrower than the output pulse width T_p to assure proper resetting of the Q9-Q11 flip-flop.

The output pulse of the one-shot performs three functions during the timing interval:

1. The open-collector output transistor Q32 is switched into saturation. The output pulse at pin 3 is in the low state during the T_p timing interval.
2. A reference voltage V_R is switched ON at pin 2.
3. The output current source is gated ON. A current pulse of width T_p and amplitude V_R/R_S will come out of pin 1.

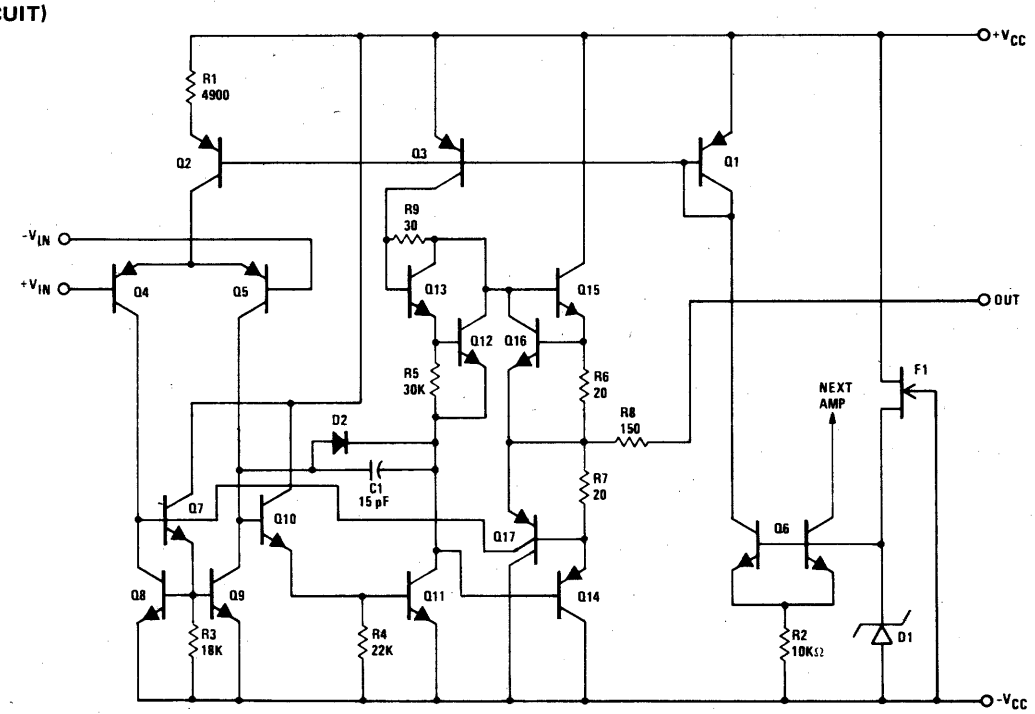
DESCRIPTION

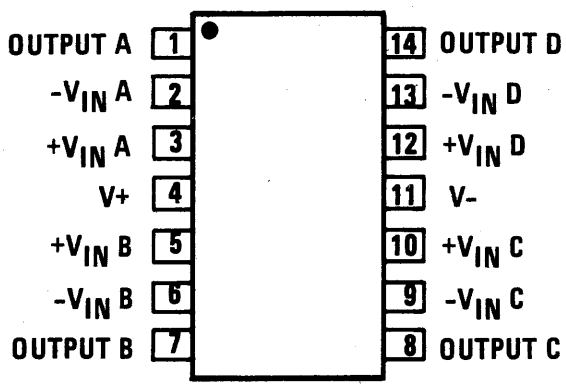
The RM4156/RC4156 is a monolithic integrated circuit, consisting of four independent high performance operational amplifiers constructed with the planar epitaxial process.

These amplifiers feature guaranteed A.C. performance which far exceeds that of the 741 type amplifiers. Also featured are excellent input characteristics and guaranteed low noise making this device the optimum choice for audio, active filter and instrumentation applications.



FEATURES

	Typical	Guaranteed
• Unity Gain Bandwidth	3.5 MHz	2.8 MHz
• High Slew Rate	1.6V/μS	1.3V/μS
• Low Noise Voltage	0.8μV	2.0μV



- Indefinite Short Circuit Protection
- No Crossover Distortion
- Low Input Offset and Bias Parameters
- Internal Compensation
- Pin-for-pin equivalent to LM324, LM348, HA4741

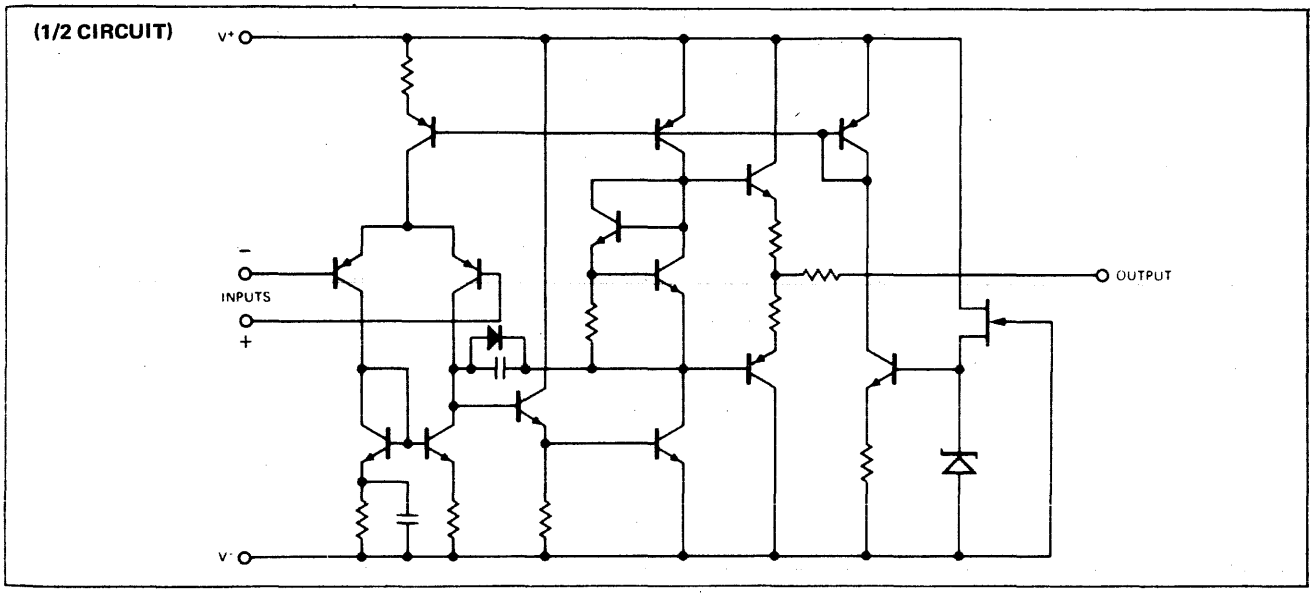
GENERAL DESCRIPTION

The 4559 integrated circuit is a high performance operational amplifier internally compensated and constructed on a single silicon chip using the planar epitaxial process.



These amplifiers feature guaranteed AC performance which far exceeds that of the 741 type amplifiers. The specially designed low noise input transistors allow the 4559 to be used in low noise signal processing applications such as audio pre amplifiers and signal conditioners.

FEATURES

DF322

CMOS LOOP DISCONNECT DIALER CIRCUITS

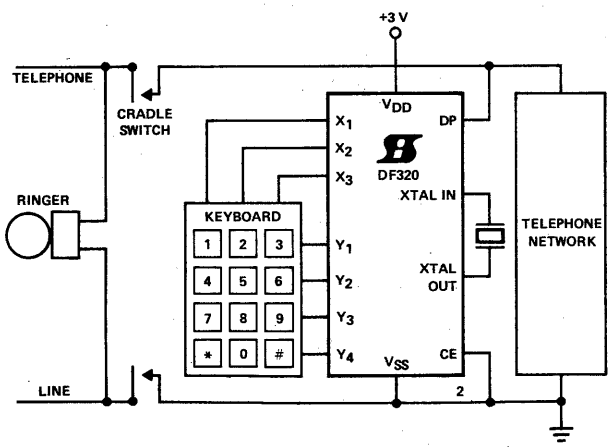
D SUFFIX: –40 to +85°C
OPERATING TEMPERATURE RANGE

Description

The DF320 series of monolithic CMOS Loop Disconnect Diallers each contain all the logic necessary to interface a standard double contact keyboard to a telephone system requiring loop disconnect signalling.

A dial pulsing output and two masking output options are provided to control the impulsing (loop disconnect) and muting functions. The circuit is capable of storing a number string of up to 20 digits and re-dialling this stored number automatically at a later time, initiated by a RE-DIAL input code. Impulsing mark/space ratio (M/S), impulsing rate and interdigital pause (IDP) are all pin programmable to meet most telephone authority specifications.

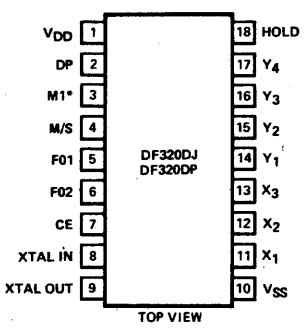
The use of Siliconix low voltage CMOS technology allows operation with an unregulated supply voltage down to a guaranteed minimum of 2.5 V. This feature, together with low operating current, negligible standby current and high noise immunity make the DF320 series easy to interface from long telephone lines.



External component count is minimized by the inclusion of an on-chip clock oscillator, high impedance pull-down terminations to programming inputs as well as pull-up terminations to the keyboard giving direct interfacing.

The Loop Disconnect Dialler is available in three pinout options. The DF320 provides the functions most commonly required in the push button telephone application. M1 is the masking option which remains at logic "1" throughout the dialling sequence. The DF322 is identical to the DF320 except that M2 is offered instead of M1. The M2 masking option is at logic "1" only during impulsing, allowing the telephone line to be monitored during the IDP. The DF321 is a multioption version which offers both M1 and M2 together with FD, IDP and SYS CK. All versions are based on the same integrated circuit.

Features



- **Operation from 2.5 V to 5.5 V V_{DD} Supply (May Be Unregulated)**
- **Low Standby Dissipation–3 μW Typ @ 3 V Supply**
- **Low Dynamic Dissipation–540 μW Typ @ 3 V Supply**
- **On-Chip Oscillator Uses Low Cost 3.579545 MHz Crystal**
- **Power ON Reset**
- **On-Chip Pull-Up and Pull-Down Terminations to Inputs**
- **High Input Noise Immunity: Typ 45% of Supply Voltage**
- **Key Input Debounce Circuitry**
- **Fully Static Storage Up to 20 Decimal Digits**
- **Repeat of Last Number**
- **Selectable Impulsing Mark/Space Ratios of 2:1 or 3:2**
- **Selectable Impulsing Speeds of 10, 16, 20 and 932 Hz**
- **Selectable Interdigital Pause: 8 or 4 Times Impulsing Period**

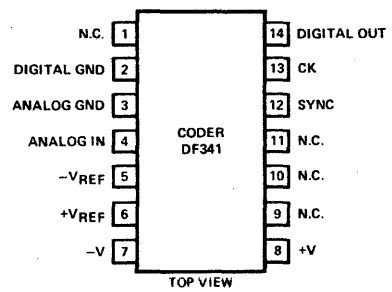
CMOS TELECOMMUNICATIONS A-LAW COMPANDER SET

Description

The DF341 (coder) is an analog-to-digital converter which has a transfer characteristic conforming to the telecommunication industry CCITT A-law. Its counterpart, the DF342 (decoder) is a digital-to-analog converter which also conforms to the A-law.



Together these parts form a codec (coder-decoder set) which is designed to meet the needs of the telecommunications industry for per channel voice frequency codecs used in PCM Channel Bank and PBX systems. Digital output and input of the coder and decoder is in serial format. Actual transmission and reception of 8-bit data words containing the analog information is done at a 2.048 megabit/sec rate with analog signal sampling occurring at an 8 kHz rate. A sync pulse input is provided for synchronizing transmission and reception of multi-channel information being multiplexed over a single transmission line.

Features

- **Low Power Dissipation**
- **Follows the CCITT A-Law for Companding**
- **Serial Data Output of 2.048 MHz at 8 kHz Sampling Rate**
- **Open Drain Digital Output Allows Easy Interface to TTL and CMOS Multiplexers**
- **Decoder Contains On-Board Sample and Hold Output**
- **Separate Analog and Digital Grounding Pins Reduce System Noise Problems**

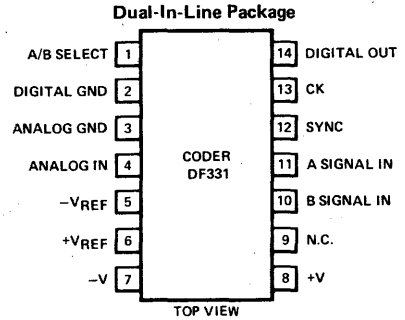
CMOS TELECOMMUNICATIONS μ-LAW COMPANDER SET

Description

The DF331 (coder) is an analog-to-digital converter which has a transfer characteristic conforming to the telecommunication industry μ-255 law. Its counterpart, the DF332 (decoder) is a digital-to-analog converter which also conforms to the μ-255 law.



Together these parts form a codec (coder-decoder set) which is designed to meet the needs of the telecommunications industry for per channel voice frequency codecs used in PCM Channel Bank and PBX systems. Digital output and input of the coder and decoder is in serial format. Actual transmission and reception of 8-bit data words containing the analog information is done at a 1.544 megabit/sec rate with analog signal sampling occurring at an 8 kHz rate. A sync pulse input is provided for synchronizing transmission and reception of multi-channel information being multiplexed over a single transmission line.

Features

- **Low Power Dissipation**
- **Follows the μ-255 Law for Companding**
- **Serial Data Output of 1.544 MHz at 8 kHz Sampling Rate**
- **Active Low Open Drain Digital Output Allows Easy Interface to TTL and CMOS Multiplexers**
- **Decoder Contains On-Board Sample and Hold Output**
- **Separate Analog and Digital Grounding Pins Reduce System Noise Problems**
- **Dual Channel Signalling**
- **Zero Code Suppression**

FUNCTIONAL DESCRIPTION

Positive and Negative Reference Voltages: Analog input voltages must be between the positive and negative reference voltages for accurate coding.

Analog Input: Voice frequency analog signals which are bandwidth limited to below 4 kHz are inputted at this pin. These analog signals are then sampled at an 8 kHz rate for approximately 31 μsec.

Fast Clock: A fast clock input is provided on the DF331 and DF332. This clock is used for the high speed data transmission needed in PCM Channel Bank and PBX systems, and is internally divided to provide timing and control. The on-chip 8 bit output shift register of the coder is unloaded at this fast clock rate while the input register of the decoder is loaded at this rate. A 1.544 MHz rate is standard for use in 24 channel PCM systems. A 32-channel system would require a 2.048 MHz clock. Both parts will operate at this higher clock rate.

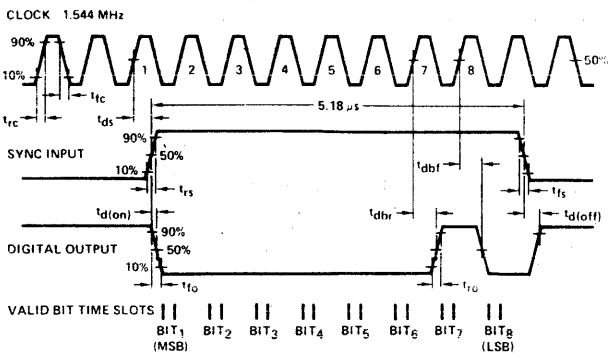
Sync: In order to synchronize many channels into one data stream, a method of controlling the dumping and loading of the output and input shift registers of the individual coders and decoders is necessary. This is accomplished through the use of an externally generated sync pulse presented to the sync input pin. This pulse occurs at an 8 kHz rate and is synchronized to the fast clock. Its duration is 8 fast clock cycles.

Upon receiving a sync pulse the coder will dump the contents of the output shift register at the fast clock rate. The decoder upon reception of the sync will load its input register at the fast clock rate.

Digital Output: The coder output register stores the 8 bit encoded sample of the analog input. This 8 bit word is shifted out of the coder via an open drain output device in serial format. Open drain output allows easy interfacing to CMOS and TTL multiplexers.

Digital Input: The digital input of the decoder accepts an 8 bit word into the input shift register upon the decoder's reception of a sync pulse.

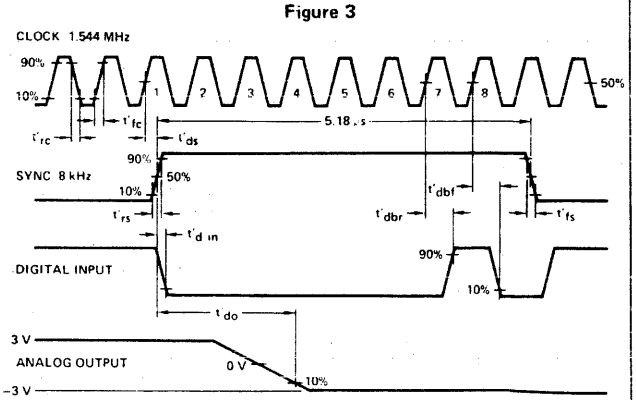
Analog Output: The analog output of the decoder is in the form of voltage pulses having a duration of 8 fast clock cycles and amplitude equal to the analog sample which was encoded. These pulses are then filtered with an active low pass filter to recreate the actual sampled voice signal.



Signal Bit Inputs A and B: Two signaling bit inputs A and B are provided on the DF331 allowing insertion of signaling information into the transmitted data stream. This information occurs as the 8th bit in the transmitted word. A positive transition occuring on the A/B select input selects the A signaling input while a negative transition selects the B signaling input. Information presented to these inputs is inverted upon transmission. See Figure 4.

Signaling Bit Outputs A and B: Two outputs on the DF332 are provided to output received signaling information. A transition occuring on the A/B select determines whether the received signaling information is routed to the A or B output. The signaling information is present at the outputs immediately after reception.

A/B Select Input: The A/B Select Input is provided on both the DF331 and DF332 in order to select the A or B paths for the signaling information. It is a transition sensitive input. A positive transition will select path A and a negative transition will select path B. See Figure 4.



Zero Code Suppression: Should an all zeroes code result from the A to D Conversion of the sampled input (and the insertion of the signalling bit, if appropriate) bit 7 is forced to a one.

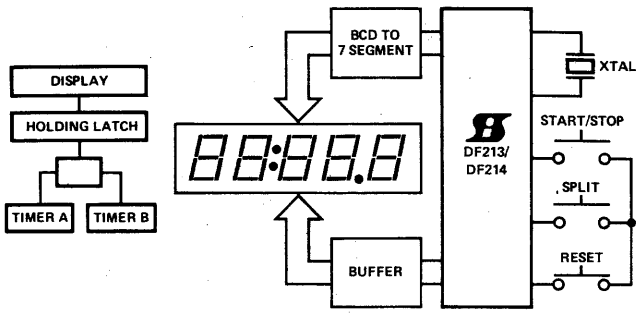
DF213 DF214

OPERATING TEMPERATURE RANGE:
C SUFFIX 0 to +70°C

DIGITAL STOPWATCH



Description

The DF213 and DF214 are P-Channel MOS devices containing all the necessary logic to implement several configurations of a digital stopwatch. A 3.2768 MHz crystal oscillator provides an extremely accurate time reference. Each device contains two timers that operate independently.

The holding latch is updated continuously from timer A or timer B or it can "freeze" the display time at a touch of a button. This configuration allows versatile event timing with "split" capability normally requiring skilled manipulation of two stopwatches. The DF213 times in minutes, seconds, and hundredths of a second providing up to six digits of display. The DF214 times in minutes and thousandths of a minute providing five digits of display.

Applications

- **Sports Timing – Auto Racing, Track, Swimming, Rodeo, Sailing, Football, Soccer**
- **Industrial Timing – Testing, Time-Motion Studies, Process Timing**
- **Scientific Timing – Chemical Reaction Timing, Mechanical Stress Timing, Animal Behavior Studies**

DF215

OPERATING TEMPERATURE RANGE:
C SUFFIX 0 to +70°C

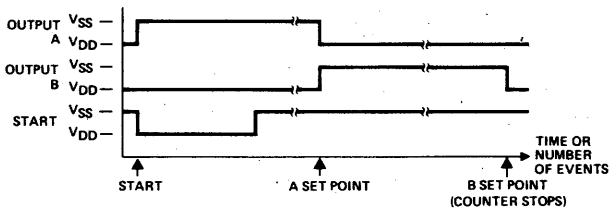
DUAL SET POINT TIMER/COUNTER

Description

The DF215 is a P-channel, depletion load MOS device containing all the necessary logic to implement a single or dual set point timer or counter. The device typically uses one or two thumbwheel switch banks to provide two sequential, fully selectable, accurate intervals for equipment control. Figure 1 shows the control output response. The DF215 either counts events or time intervals using a 50 Hz or 60 Hz power line time base. Multiplexed outputs provide the total elapsed time (or number of events) from start for display.

Applications

- **Industrial Process Control**
- **Commercial Food Preparation Control**
- **Automatic Feed, Fluid, or Material Dispensing**
- **Step and Repeat Control**
- **Test Timing**
- **Sporting Event Timing**



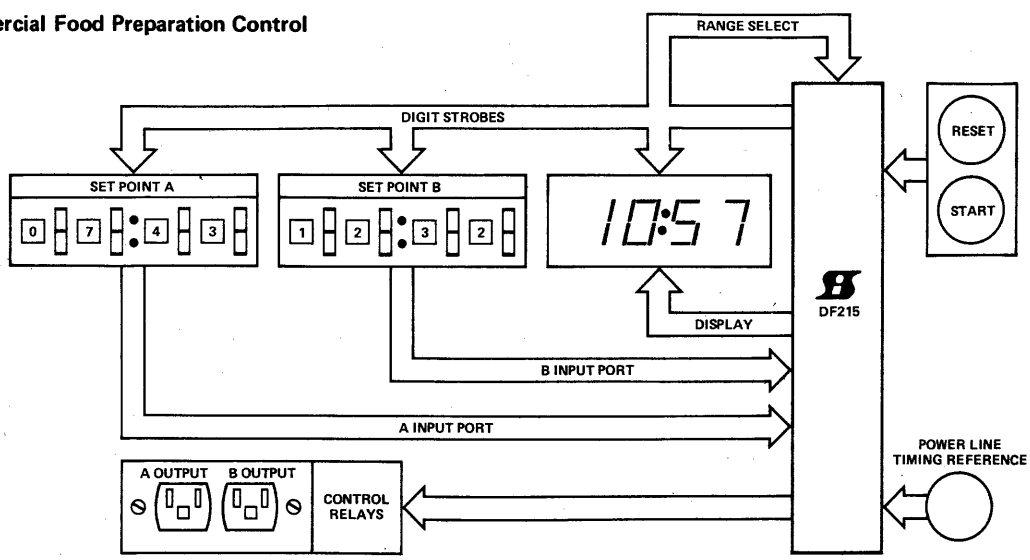


Figure 1

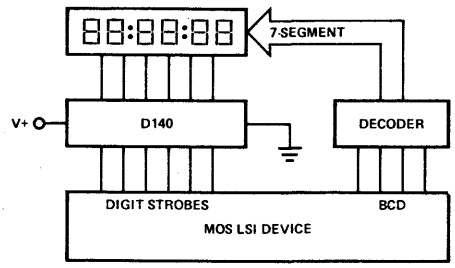


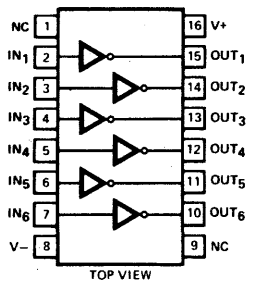
D140

OPERATING TEMPERATURE RANGE:
C SUFFIX 0 to +70°C

HEX DIGIT DRIVER

Description

The D140 is a Hex Driver intended as a digit driver for common cathode LED displays. The D140 has the advantage over other driver types of very low voltage operation and high current gain. The D140 is well suited to driving loads on the order of 100 mA from low current CMOS devices. Fast switching speeds (250 ns) and low input bias currents (80 μA) make the D140 well suited to applications such as clock drivers and hand-held instruments.



Applications

- Relay Drivers
- Common Cathode Digit Drivers
- Common Anode Segment Drivers
- CMOS to TTL Level Translators

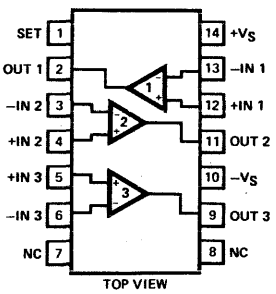
L144

MICROPOWER TRIPLE OPERATIONAL AMPLIFIER

Description



The L144 is a monolithic low-power triple operational amplifier stabilized for all feedback configurations and capacitive loads by internal gain compensation. Low power requirements permit high voltage operation across the rated temperature range, as well as battery operation from ±1.5 V.

Features

- External Control of Supply Current and Output Drive
- Operation With ±1.5 V to ±15 V Power Supplies
- 80 dB Gain With 20K Ω Load
- ±30 V Differential Input Voltage Range
- Drives Large Capacitive Loads (> 1000 pF)
- Internally-Compensated
- Continuous Short-Circuit Protection
- Monolithic Construction
- Slew Rate 0.4 V/μs Typical

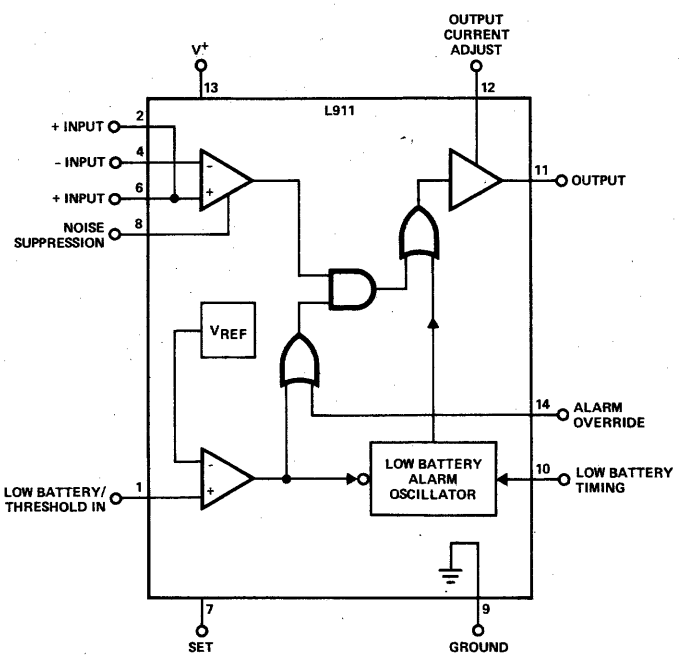
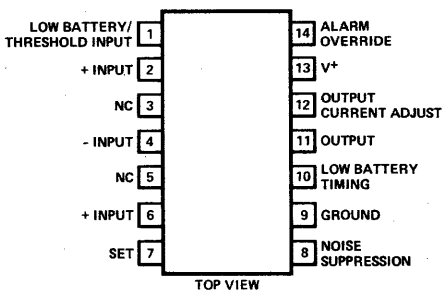
MICROPOWER COMPARATOR, DETECTOR ALARM CIRCUIT

MONOLITHIC INTEGRATED CIRCUIT FOR DETECTOR AND ALARM SYSTEMS



Description

The L911 is a monolithic bipolar-PMOS integrated circuit intended to meet the system requirements of a micropower detector alarm or ON/OFF control system. The circuit will operate from a supply as low as 6V and is tested for 15V conditions. The alarm output can source sufficient current to activate an NPN or SCR buzzer alarm driver and can also interface to TTL or CMOS logic. The L911 can easily operate with a standby supply current of less than 10 μA from a 9 V battery, and less than 17 μA at 15 V. The high input impedance MOSFET comparator easily interfaces to high impedance sensor devices.



Features

- **High Input Impedance MOS FET Comparator**
- **Low Standby Current Drain (< 10 μA) Allows Greater than 1 Year Battery Life**
- **Operation from a 6 V to 15 V Power Source**
- **Includes Low Battery/Threshold Voltage Detection Circuitry**
- **Built-In Reverse Battery Protection**
- **Outputs to SCR or NPN for Driving Buzzer Alarm**
- **TTL or CMOS Logic Compatible Output**
- **Low Input Bias Current (I_{IN} < 10 nA)**
- **Wide Common Mode Input Range**
- **Output Sourcing Current Adjustable Up to 30 mA**
- **Adjustable Timing of "Trouble Signal" Pulses**
- **Allowance for Input Noise Suppression**
- **Can be Used in a Latching or Non-Latching System**

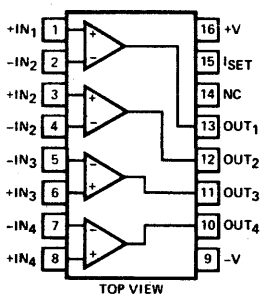
MICROPOWER QUAD COMPARATOR

Description



The L161 is a monolithic quad micropower comparator circuit, with an external control for varying supply current, input bias current and output current drive. This is accomplished by a single resistor connected to V+ which controls the bias current to Q_{10} which via a series of current mirrors supplies bias to the differential amplifier. The L161 finds applications in areas where low powered battery operation and CMOS compatibility are required. The ability to control comparator characteristics makes this a very versatile device.

Features

- **Power Dissipation as Low as 15 μW**
- **External Control of Supply Current and Output Drive**
- **Operation with ±1.5 V to ±18 V Power Supplies**
- **Single Supply Operation**
- **Gain Greater than 20K**
- **Sensing Near Ground**
- **±36V Differential Input Voltage Range**
- **Slew Rate 3 V/μs Typical**
- **CMOS Logic Compatible**
- **Operation in Low and High Power Modes**

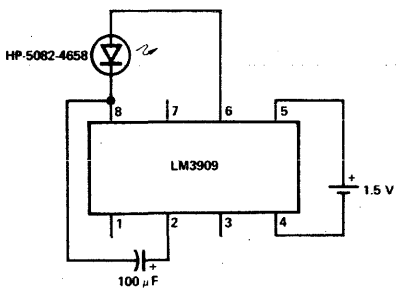
LM3909

MICROPOWER LED FLASHER

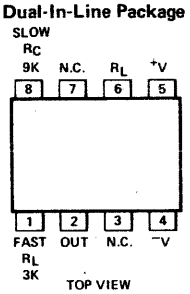
OPERATING TEMPERATURE RANGE:
–25° to +70°C



Description

The LM3909 is a monolithic oscillator specifically designed to flash Light Emitting Diodes. By using the timing capacitor for voltage boost, it delivers pulses of 2 or more volts to the LED while operating on a supply of 1.5 V or less. The circuit is inherently self-starting, and requires the addition of only a battery and capacitor to function as an LED flasher.

Features



- **Operation Over One Year From One C Size Flashlight Cell**
- **Bright, High Current LED Pulse**
- **Minimum External Parts**
- **Low Cost**
- **Low Voltage Operation, From 1.15 V to 6 V**

Minimum Power at 1.5V

description

The JFET-input operational amplifiers of the TL061 series are designed as low-power versions of the TL081 series amplifiers. They feature high input impedance, wide bandwidth, high slew rate, and low input offset and bias currents. The TL061 series feature the same terminal assignments as the TL071 and TL081 series, except the TL066 has an additional power control function (pin 8) that allows the user to control the power dissipation of the circuit. This is achieved by connecting a resistor between the power-control terminal and V_{CC-}. For normal operation, the power-control terminal is connected directly to V_{CC-}.

Device types with an "M" suffix are characterized for operation over the full military temperature range of –55°C to 125°C, those with an "I" suffix are characterized for operation from –25°C to 85°C, and those with a "C" suffix are characterized for operation from 0°C to 70°C.

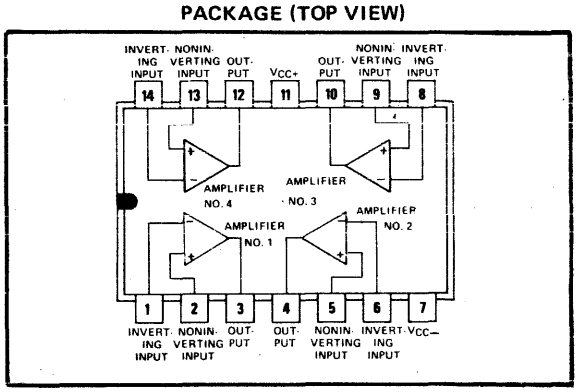
description



The JFET-input operational amplifiers of the TL071 series are designed as low-noise versions of the TL081 series amplifiers with lower input bias current, offset current, and offset voltage. The low harmonic distortion and low noise make the TL071 series ideally suited as amplifiers for high-fidelity and audio preamplifier applications. Each amplifier features JFET-inputs (for high input impedance) coupled with bipolar output stages all integrated on a single monolithic chip.

Device types with an "M" suffix are characterized for operation over the full military temperature range of −55°C to 125°C, those with an "I" suffix are characterized for operation from −25°C to 85°C, and those with a "C" suffix are characterized for operation from 0°C to 70°C.

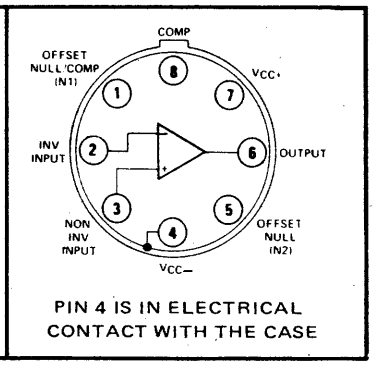
description

The TL081 JFET-input operational amplifier family is designed to offer a wider selection than any previously developed operational amplifier family. Each of these JFET-input operational amplifiers incorporates well-matched, high-voltage JFET and bipolar transistors in a monolithic integrated circuit. The devices feature high slew rates, low input bias and offset currents, and low offset voltage temperature coefficient. Offset adjustment and external compensation options are available within the TL081 Family.



Device types with an "M" suffix are characterized for operation over the full military temperature range of −55°C to 125°C, those with an "I" suffix are characterized for operation from −25°C to 85°C, and those with a "C" suffix are characterized for operation from 0°C to 70°C.

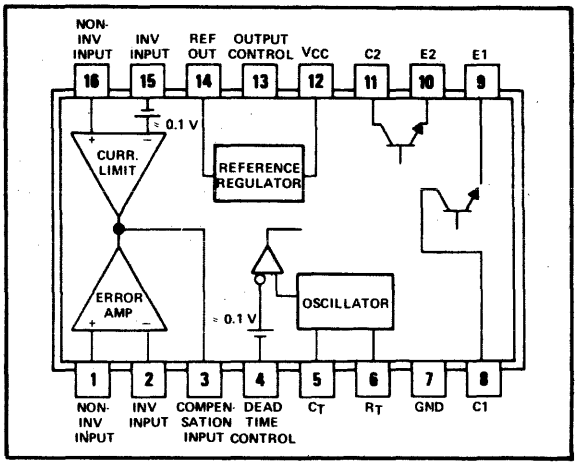
I_{CC}	Supply current (per amplifier)	No load, T_A = 25°C	No signal,		1.4	2.8		1.4	2.8		1.4	2.8	mA
V_{o1}/V_{o2}	Channel separation	A_{VD} = 100,	T_A = 25°C		120			120			120		dB

† All characteristics are specified under open-loop conditions unless otherwise noted. Full range for T_A is −55°C to 125°C for TL08_M and TL08_AM; −25°C to 85°C for TL08_I; and 0°C to 70°C for TL08_C, TL08_AC, and TL08_BC.

‡ Types TL080AM and TL083AM are not defined by this data sheet.



§ Input bias currents of a FET-input operational amplifier are normal junction reverse currents, which are temperature sensitive. Pulse techniques must be used that will maintain the junction temperature as close to the ambient temperature as is possible.

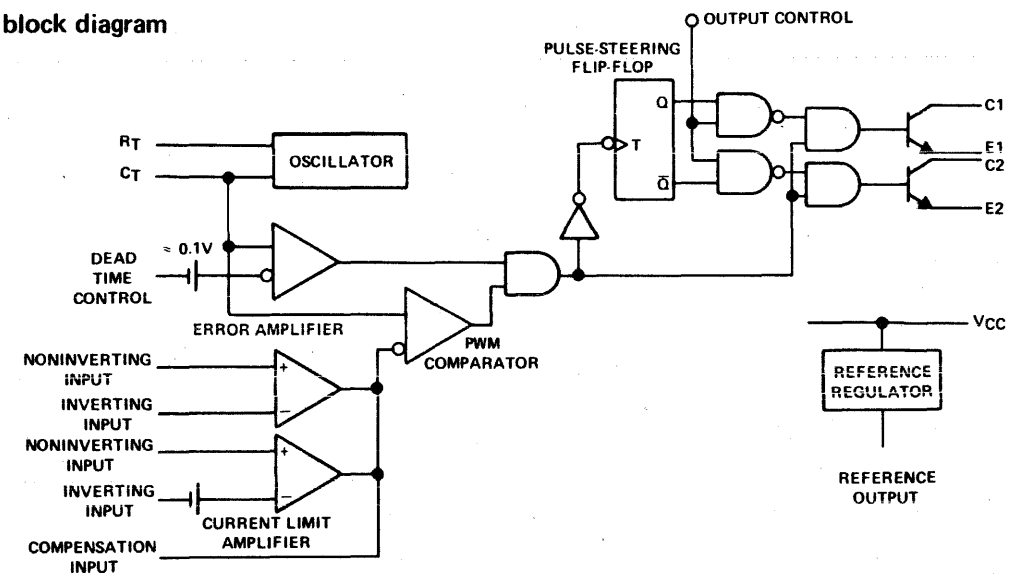
SEPTEMBER 1977

- Complete PWM Power Control Circuitry
- Uncommitted Outputs for Single-Ended or Push-Pull Operation
- Internal Circuitry Prohibits Double Pulse at Either Output
- Variable Dead-Time Control . . . 45% to 0% at Each Output
- Oscillator Capable of Stand-Alone or Driven Operation

TL494M . . . J
TL494I, TL494C . . . J OR N
DUAL-IN-LINE PACKAGE
(TOP VIEW)



description

The TL494 incorporates on a monolithic chip all the functions required for pulse-width-modulation control circuits. Designed primarily for power supply control, the TL494 has an on-chip 5-volt regulator, error amplifier, current-limit amplifier, adjustable oscillator, dead time control comparator, pulse-steering flip-flop, and output control circuitry. The uncommitted output transistors may be operated common-collector or common-emitter. Internal circuitry provides output control for either complementary or tandem operation. The trigger for the pulse-steering flip-flop is derived from the pulse-width-modulation circuit to prevent double-pulsing of either output. Both the error amplifier and the current-limit amplifier have a common-mode input voltage range from −0.2 volt to V_{CC} − 1.5 volts. Fixed internal offsets provide a current-limit sense threshold of 0.1 volt for the current-limit amplifier and a 45% maximum duty cycle for the dead time control comparator. The oscillator can be programmed by passive components or driven by a master oscillator. The versatility of the TL494 makes it suitable for a variety of PWM applications including switching regulators (of either polarity) and dc-to-dc converters (with or without transformer-coupled outputs).

The TL494M will be characterized for operation over the full military temperature range of −55°C to 125°C. The TL494I will be characterized for operation from −25°C to 85°C, and the TL494C will be characterized for operation from 0°C to 70°C.

we know

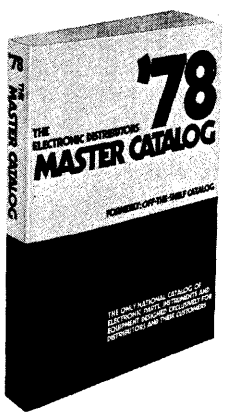
40 years of experience in

United Electronics

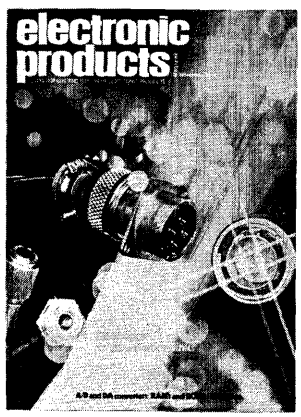
eem/ELECTRONIC ENGINEERS MASTER CATALOG —

The "blue-ribbon" catalog/directory that has become "the standard of the industry" for electronic engineers, buyers and specifiers.

ELECTRONIC ENGINEERS CATALOGUE —



The new catalogue/directory of electronic products available to and from Western Europe and the United Kingdom. Designed especially for the European electronics engineer.



IC MASTER AND THE UPDATES —

The only complete single-source directory including all IC devices manufactured in the United States. Updated three times yearly with accumulative supplements.

our stuff...

cataloging, 20 editions of eem Technical Publications Division

ELECTRONIC DISTRIBUTORS MASTER CATALOG —

(Formerly O-T-S Catalog) The only national catalog designed exclusively for distributors and their customers featuring electronic parts, instruments and equipment.

ELECTRONIC PRODUCTS MAGAZINE —

The products magazine . . . A 100% product-oriented magazine including hundreds of new products and special features every month.

eem FILE SYSTEM —

The only filing system designed specially for the electronics engineer. Instant retrieval and organization of data sheets and catalogs.

UNITED COST AND PRICING SERVICES —

The electronic distributors' proven method of being up to the minute on his cost and selling prices.

UTP CUSTOM CATALOGS —

The Cadillac of individualized catalogs for the electronic parts distributor, featuring solely his lines and services.

NEC Microcomputers	1375
Raytheon Semiconductor	1493

The manufacturers listed above are providing detailed information on their latest and most significant products. They have made this investment to help you.

MEMORY.....

The Master Selection Guide provides sufficient information to make initial product selections, to lead you to a group of device numbers and manufacturers' names. It enables you to find the products which are most appropriate to fulfill your major requirements and then provides data for many of the more important products.

All devices that appear in this section, both in the initial selection guide and in the data pages, are included in the Part Number and Product Indexes. These index listings lead to the page and the line on that page where each device appears.

The Memory Section provides initial selection information and data on PROMs, RAMs, and ROMs as well as other memory devices. In these particular sections, the devices are characterized by organization (words and bits/word) and by access times. In order to assure that the access times are comparable, whenever possible the values have been shown in nanoseconds over the full rated temperature range for the devices (i.e., 0° to 70°C for commercial units and −55°C to 125°C for military units). The full temperature nanosecond value is marked "nsF." When this value isn't specified, the guaranteed nanosecond value at room temperature is listed followed by "nsR." In some cases a guaranteed value has not yet been established; then the typical value is shown followed by "ns," "* ". "Typical" values are invariably much faster than the guaranteed ones so that such listings place these memories higher on the list than they otherwise would appear.

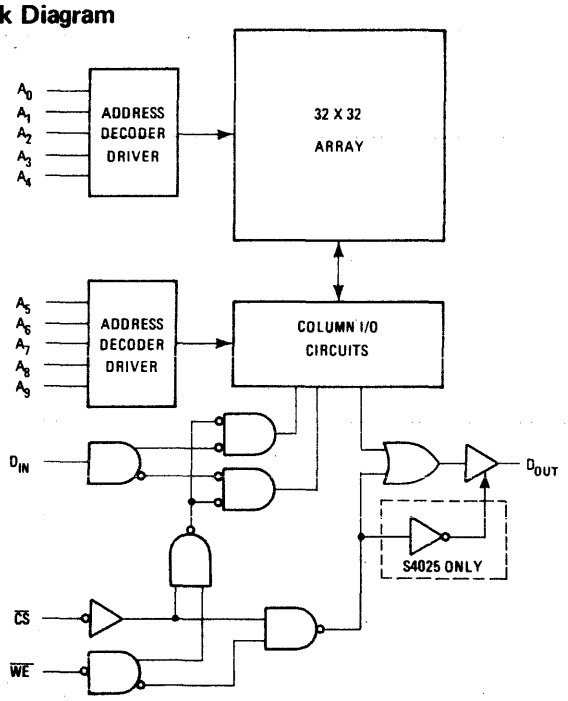
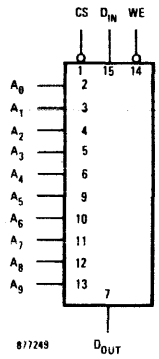
Input Voltages	-0.5V to +5.5V
Power Dissipation	1 Watt



General Description

The AMI S4015/S4025 family of 1024x1 bit high spe VMOS RAMs offers fully static operation with a single supply. The device is completely TTL compatible on inputs and output. The family is available in two outp configurations. The S4015 has an open collector (op drain) output and the S4025 has a three state output. T stored data is read out nondestructively and is the sa polarity as the original input data.

The family is completely static requiring no clocks or freshing for operation. Chip Select (CS) controls the o put and simplifies memory system expansion. The f chip select time allows decoding the chip select from address without increasing address access time.



The S4015/S4025 is fabricated using AMI's propriet VMOS process, thus allowing the production of high spe MOS RAMs that are fully compatible with bipolar RA but offering the advantage of lower power dissipation.

VMOS—The New Technology from AMI

VMOS is the patented new technology developed by AMI to produce low-cost, high-density integrated circuits with a process that yields products with very high operating speeds. VMOS has literally opened up a new dimension in the design and manufacture of electronic memory and other circuits for large computer systems, minicomputer systems, microcomputers, microprocessors and hundreds of other applications for consumer and communications products employing large scale integrated circuits.

The first product manufactured at AMI using the VMOS technology was the S4015 1Kx1 static RAM. Having proved the viability of VMOS for static RAMs, AMI started numerous designs in both random access memories and read only memories. These new designs will also undergo extensive quality and reliability tests.

The secret of VMOS is a process which produces tens of thousands of transistors in an integrated circuit as tiny V-shaped grooves. The acronym "VMOS" stands for V-groove Metal-Oxide-Silicon. Metal, oxide and silicon comprise the layers making up the transistors in the most widely manufactured types of LSI circuits. The VMOS process, unlike others, deposits these layers into the small three-dimensional grooves rather than over a larger two-dimensional area on the small piece of silicon that comprises a complete integrated circuit.

The VMOS process produces very small circuits hence many more per wafer than competitive processes such as N-channel MOS and digital bipolar. Because VMOS takes advantage of the third dimension of the wafer and employs special processing techniques, VMOS transistors are smaller than competing types of technologies. The result is high density VMOS circuits which are very fast and as much as 50 percent smaller (and more economical) than circuits made with other technologies.

Ordering Information

Any product in this Condensed MOS Products Catalog can be ordered using the simple system described below. With this system it is possible to completely specify any standard device in this catalog in a manner that is compatible with AMI's order processing methods. The example below shows how this ordering system works and will help you to order your parts in a manner that can be expedited rapidly and accurately.

All orders (except those in sample quantities) are normally shipped in plastic carriers or aluminum tube containers, which protect the devices from static electricity damage under all normal handling conditions. Either container is compatbile with standard automatic IC handling equipment.

Any device described in this catalog is an AMI Standard Product. However, ROM devices that require mask preparation or programming to the requirements of a particular user, devices that must be tested to other than AMI Quality Assurance standard procedures, or other devices requiring special masks are sold on a negotiated price basis.

S 6 8 2 0 A — 1 P

Device Number — prefix S, followed by four numeric digits that define the basic device type. If there are versions to the basic device, the four numeric digits will be followed by additional alphanumeric digits, in this example A-1. The last digit should always be followed by a space.

Package Type — a single letter designation which identifies the basic package type. The letters are coded as follows:

P — Plastic package

E — Cer-DIP package

S — SLAM package

C — Ceramic (three-layer) package

T — TO type package

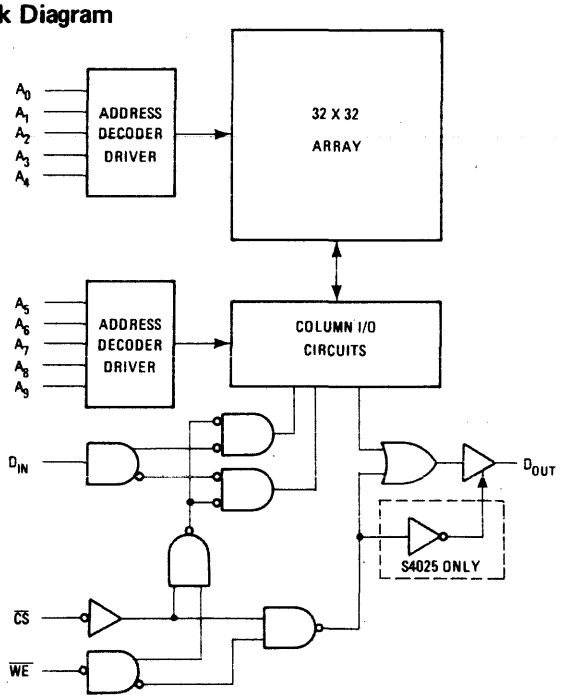
1024 Bit (1024×1) Static High Speed VMOS RAM

Features

- Pin Compatible with 93415 (S4015) and 93425 (S4025)
- Single +5V Supply
- Directly TTL Compatible
- Open Collector Output — S4015
- Three State Output — S4025
- Fan-Out of 10 TTL — I_{OL} = 16mA @ 0.45V
- Completely Static — No Clocks or Refreshing

Absolute Maximum Ratings*

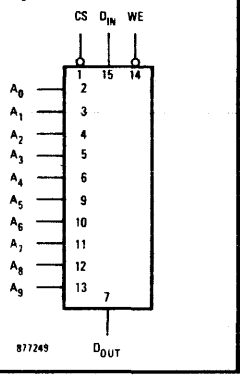
Ambient Temperature Under Bias	-10° C to +85° C
Storage Temperature	-65° C to +150° C
Output or Supply Voltages	-0.5V to +7V
Input Voltages	-0.5V to +5.5V
Power Dissipation	1 Watt



General Description

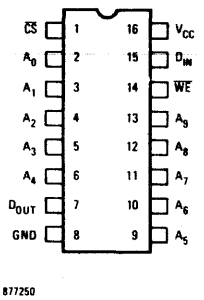
The AMI S4015/S4025 family of 1024x1 bit high speed VMOS RAMs offers fully static operation with a single 5V supply. The device is completely TTL compatible on all inputs and output. The family is available in two output configurations. The S4015 has an open collector (open drain) output and the S4025 has a three state output. The stored data is read out nondestructively and is the same polarity as the original input data.

The family is completely static requiring no clocks or refreshing for operation. Chip Select (CS) controls the output and simplifies memory system expansion. The fast chip select time allows decoding the chip select from the address without increasing address access time.



The S4015/S4025 is fabricated using AMI's proprietary VMOS process, thus allowing the production of high speed MOS RAMs that are fully compatible with bipolar RAMs but offering the advantage of lower power dissipation.

Block Diagram



*COMMENT: Stresses above those listed under "Absolute Maximum Rating" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other condition above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

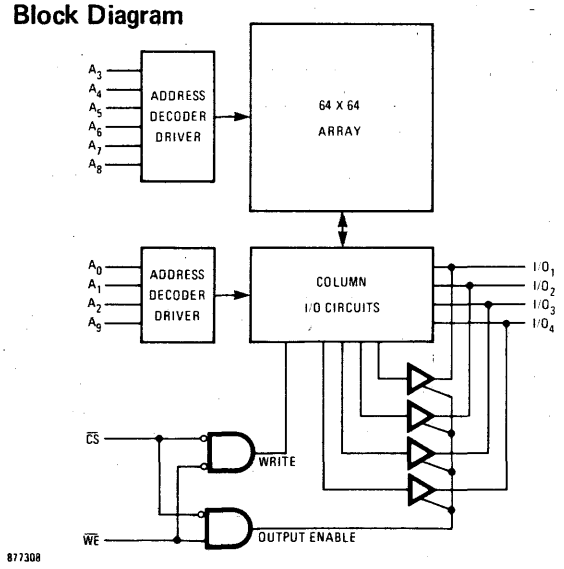
4096 Bit (1024×4) Static VMOS RAM

Features

- ☐ High Density 18 Pin Package
- ☐ Single +5V Supply
- ☐ Completely Static Operation: No Clocks Required
- ☐ Completely TTL Compatible
- ☐ Common Data I/O: Three State Outputs
- ☐ High Speed Operation: Access Time: 200ns Maximum
- ☐ Fan-Out of 5 TTL – I_{OL} = 8mA @ 0.4V

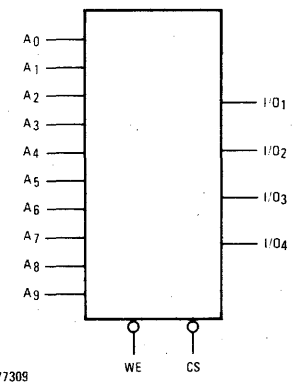
Absolute Maximum Ratings*

Ambient Temperature Under Bias	-10°C to 80°C
Storage Temperature	-65°C to 150°C
Voltage on Any Pin With Respect to Ground	-0.5V to 7V
Power Dissipation	1W



General Description

The AMI S4016 is a 4096 bit fully static RAM organized as 1024 words by 4 bits. The device is fully TTL compatible on all inputs and outputs and has a single + 5V supply. The common data input/output pins facilitate interface with systems utilizing a bidirectional data bus. The stored data is read out non-destructively and is the same polarity as the original input data.



The S4016 is fully static requiring no clocks or refreshing for operations. This simplifies device operation as no address setup times are required. The chip select function facilitates memory system expansion by allowing the input/output pins to be OR-tied to other devices.

The S4016 is fabricated using AMI's proprietary VMOS technology. This process permits the manufacture of high performance memory devices suitable for high volume production.

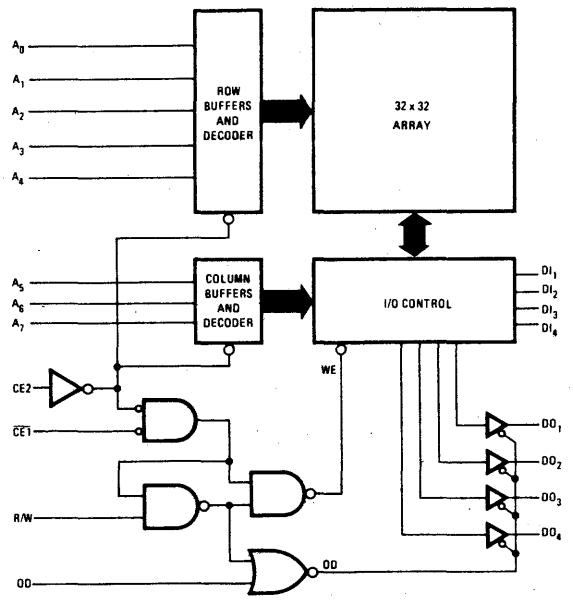
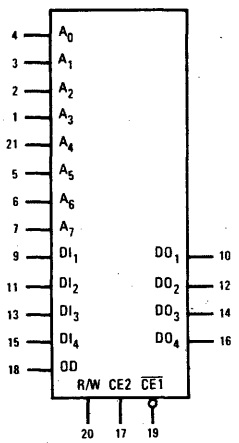
1024 Bit (256×4) Static CMOS RAM



Features

- ☐ Ultra Low Standby Power
- ☐ Data Retention at 2V (5101L)
- ☐ Single +5 Volt Power Supply
- ☐ Completely Static Operation
- ☐ Completely TTL Compatible Inputs
- ☐ Three-State TTL Compatible Outputs



General Description

The AMI S5101 family of 256 x 4-bit ultra low power CMOS RAMs offers fully static operation with a single + 5 volt power supply. All inputs and outputs are directly TTL compatible. With data inputs and outputs on adjacent pins, either separate or common data I/O operations can easily be implemented for maximum design flexibility. The three-state outputs will drive one full TTL load and are disabled (high impedance state) by output disable (OD), either chip enable ($\overline{CE1}$ or CE2), or in a write cycle (R/W = LOW). This facilitates the control of common data I/O systems.

©IC MASTER 1978

General Description (Continued)

The stored data is read out nondestructively and is the same polarity as the original input data. The S5101 is totally static, making clocks unnecessary for a new address to be accepted. The device has two chip enable inputs ($\overline{CE1}$ and CE2) allowing easy system expansion. CE2 disables the entire device but $\overline{CE1}$ does not disable the address buffers and decoders. Thus, minimum power dissipation is achieved when CE2 is low.

When deselected (CE2 = LOW), the S5101 draws less than 10 microamps from the 5 volt power supply. The S5101L is identical to the S5101 but has the additional feature of guaranteed data retention with the power supply as low as 2 volts. This makes the device an ideal choice when battery augmented non-volatile RAM storage is mandatory.

The S5101 is fabricated using a silicon gate CMOS process suitable for high volume production of ultra low power, high performance memories.

Absolute Maximum Ratings*

Ambient Temperature Under Bias	-10°C to 80°C
Storage Temperature	-65°C to 150°C
Voltage on Any Pin with Respect to Ground	-0.3V to V_{CC} +0.3V
Maximum Power Supply Voltage	11V
Power Dissipation	1W

*COMMENT: Stresses above those listed under "Absolute Maximum Rating" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or at any other condition above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

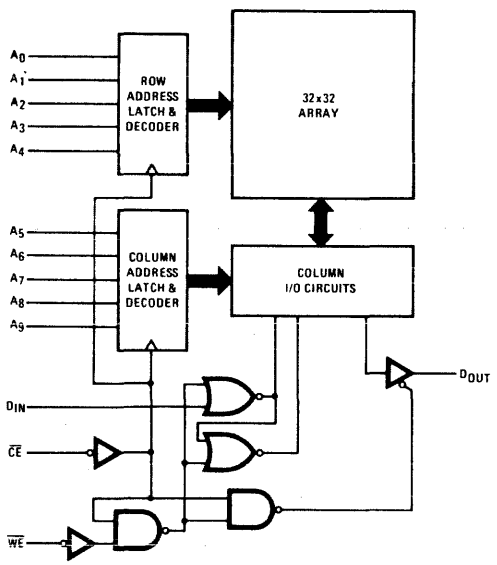
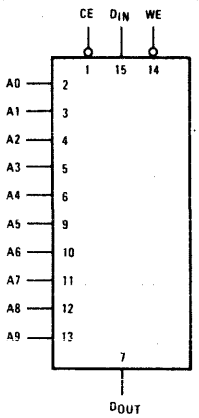
1024 Bit (1024×1) Static CMOS RAM



Features

- ☐ Ultra Low Standby Power
- ☐ S6508 Completely TTL Compatible
- ☐ S6508A Completely CMOS Compatible
- ☐ 4V to 11V Operation (S6508A)
- ☐ Data Retention at 2V
- ☐ Three-State Output
- ☐ Low Operating Power: 10mW @ 1MHz (5V)
- ☐ Fast Access Time: 115ns @ 10V



General Description

The AMI S6508 family of 1024x1 bit static CMOS RAMs offers ultra low power dissipation with a single power supply. The device is available in two versions. The basic part (S6508) operates on 5V and is directly TTL compatible on all inputs and the three-state output. The S6508 "A" operates from 4V to 11V and is fully CMOS compatible. The data is stored in ultra low power CMOS static RAM cells (six transistor). The stored data is read out nondestructively and is the same polarity as the original input data. The address is buffered by on-chip address registers. These internal registers are latched by the HIGH to LOW transition of chip enable ($\overline{CE}$). The write enable and chip enable functions are designed such that either separate or common data I/O operations can be easily implemented for maximum design flexibility.

General Description (Continued)

The S6508 is fabricated using a silicon gate CMOS process suitable for high volume production of high performance, ultra low power memories. When deselected ($\overline{CE}$ = HIGH), the S6508-1 draws less than 10 microamps from the 5V supply. In addition, it offers guaranteed data retention with the power supply as low as 2 volts. This process makes the device an ideal choice where battery augmented nonvolatile RAM storage is mandatory.

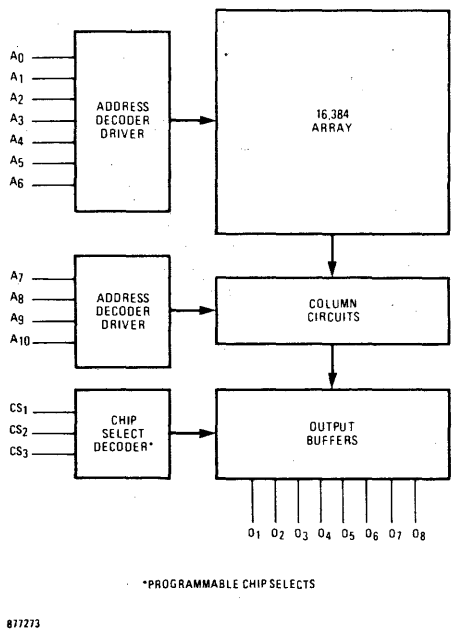
16,384 Bit (2048×8) Static VMOS ROM

Features

- ☐ Fast Access Times: 250 ns Maximum
- ☐ Fully Static Operation
- ☐ Single +5V ±10% Power Supply
- ☐ Directly TTL Compatible Inputs
- ☐ Three-State TTL Compatible Outputs
- ☐ Three Programmable Chip Selects
- ☐ EPROM Pin Compatible
- ☐ Fan-out of 5 TTL — I_{OL} = 8mA @ 0.4V

Absolute Maximum Ratings*

Ambient Temperature Under Bias	-10°C to 80°C
Storage Temperature	-65°C to 150°C
Output or Supply Voltages	-0.5V to 7V
Input Voltages	-0.5V to 5.5V
Power Dissipation	1W



General Description

The AMI S4216B is a 16,384 bit static mask programmable VMOS ROM organized as 2048 words by 8 bits. The device is fully TTL compatible on all inputs and outputs and has a single +5V power supply. The three-state outputs facilitate memory expansion by allowing the outputs to be or-tied to other devices.

The S4216B is fully compatible with 16K UV EPROMs (+5V version) making system development much easier and more cost effective. It is fully static, requiring no clocks for operation. The three chip selects are mask programmable, the active level for each being specified by the user.

The S4216B is fabricated using AMI's proprietary n-channel VMOS technology. This permits the manufacture of very high density, high performance mask programmable ROMs.

Custom Programming

The preferred method of pattern submission is the AMI Hex format as described below, with its built-in address space mapping and error checking. This is the format produced by the AMI Assembler. The format is as follows and may be on paper tape, punched cards or other media readable by AMI.

Position	Description
1	**Start of record (Letter S)**
2	**Type of record** 0 — Header record (comments) 1 — Data record 9 — End of file record
3 — 4	**Byte Count** Since each data byte is represented as two hex characters, the byte count must be multiplied by two to get the number of characters to the end of the record. (This includes checksum and address data.) Records may be of any length defined in each record by the byte count.
5, 6, 7, 8	**Address Value** The memory location where the first data byte of this record is to be stored. Addresses should be in ascending order.
9, . . ., N	**Data** Each data byte is represented by two hex characters. Most significant character first.
N+1, N+2	**Checksum** The one's complement of the additive summation (without carry) of the data bytes, the address, and the byte count.

Example:

```
S 1 1 3 0 0 0 0 4 9 E 9 F 1 0 3 2 0 F 0 4 9 3 1 3 9 F 7 2 0 0 0 F 5 E 0 F 0 0 1 2 6
S 9 0 3 0 0 0 0 F C
```

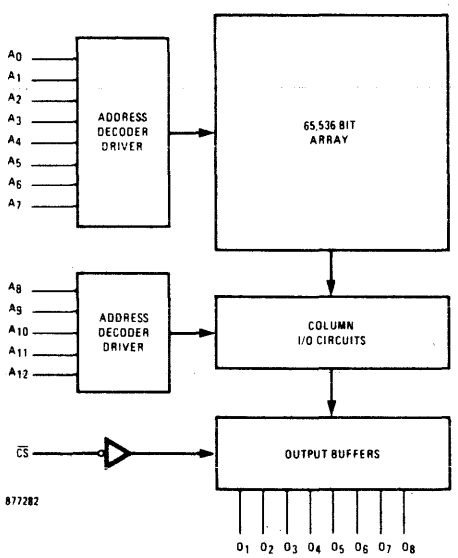
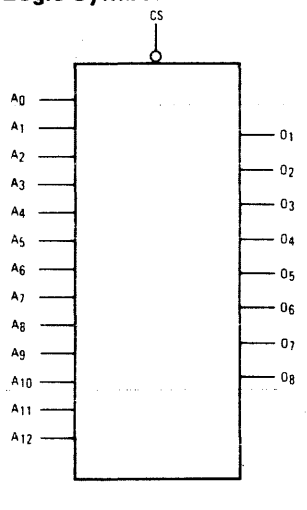
Storage Temperature	-65°C to 150°C
Output or Supply Voltages	-0.5V to 7V
Input Voltages	-0.5V to 5.5V
Power Dissipation	1W



General Description

The AMI S4264 is a 65,536 bit fully static VMOS mask programmable ROM organized as 8192 words by 8 bits. The device if fully TTL compatible on all inputs and outputs and has a single +5V power supply. The three-state outputs facilitate memory expansion by allowing the outputs to be or-tied to other devices.



The S4264 is fully static requiring no clocks for operation. The chip select ($\overline{CS}$) function is used to select the device providing for memory system expansion. The byte organization of the S4264 makes it ideal for microprocessor applications.

The S4264 is fabricated using AMI's proprietary VMOS technology. This permits the manufacture of very high density, high performance mask programmable ROMs.

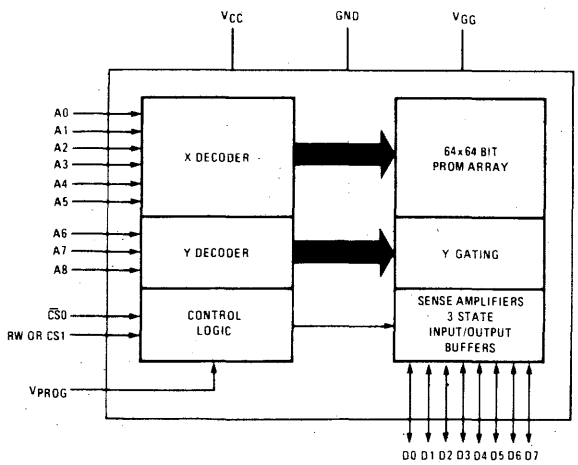
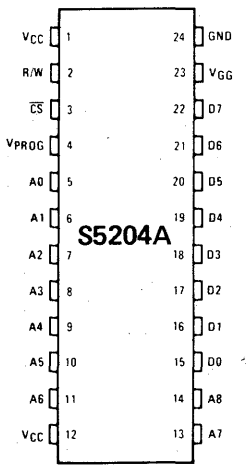
4096 Bit (512×8) Erasable and Electrically Reprogrammable ROM



Features

- ☐ On-Board Programmability
- ☐ Fast Access Time — 750ns Max.
- ☐ High Speed Programming — Less than 1 Minute for all 4096 Bits
- ☐ Programmed with R/W, CS and V_{PROG} Pins
- ☐ Completely TTL Compatible — Excluding the V_{PROG} Pin during Read or Write
- ☐ Ultraviolet Light Erasable — Less than 10 Minutes
- ☐ Static Operation — No Clocks Required
- ☐ Three-State Data I/O
- ☐ Standard Power Supplies — +5V and -12V
- ☐ Mature P-Channel Process

General Description



The S5204A is a high speed, static, 512x8 bit, erasable and electrically programmable read only memory designed for use in bus-organized systems. Both input and output are TTL compatible during both read and write modes. Packaged in a 24-pin hermetically sealed dual in-line package, the bit pattern can be erased by exposing the chip to an ultraviolet light source through the transparent lid, after which a new pattern can be written.

Block Diagram

77675

Pin Configuration

877254

ABSOLUTE MAXIMUM RATINGS

Voltage on any pin relative to V_{SS} except the V_{PROG} pin	+0.3V to -20V
Voltage on the V_{PROG} pin relative to V_{SS}	+0.3V to -60V
Operating Temperature	0°C to +70°C
Storage Temperature (programmed)	-55°C to +85°C
Storage Temperature (unprogrammed)	-55°C to +150°C

Typical Applications

- ☐ ROM Program Debugging
- ☐ Code Translation
- ☐ Microprogramming
- ☐ Look-up Tables
- ☐ Random Logic Replacement
- ☐ Programmable Waveforms
- ☐ Character Generation
- ☐ Electronic Keyboards

NOTE: This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields, however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high-impedance circuit.

INTERFACE DESCRIPTION

Pin	Label	Function
(15)	D0	**Data Lines** – with the R/W line selected for Read (V_{IH}), the Data Line (D0 through D7) are set to reflect the contents of the selected memory location. When the R/W line is set for Write (V_{IL}), the Data Lines are stored at the addressed location of the 5204A when V_{PROG} is present. The Data Bus output drivers are three-state devices that remain in the high impedance (off) state whenever CS is in the V_{IH} state or when R/W is in the V_{IL} state.

(17)	D2	
(18)	D3	
(19)	D4	
(20)	D5	
(21)	D6	
(22)	D7	
(2)	R/W	**Read/Write** – When this input line is set to V_{IH}, the device is in the Write mode, a low (V_{IL}) signal puts it into the Read mode.
(3)	CS	**Chip Select** – This input line must be set to V_{IL} for a Read or Write operation to be performed. When it is High (V_{IH}) the output data bus is set to a high-impedance three-state condition.
(4)	V_{PROG}	**Program** – In the Write mode, a 50Volt programming pulse at this input causes the data at the Data Lines to be stored in the selected address location. This pin should be tied to V_{CC} for normal Read operations.
(5)	A0	**Address Lines** – These lines select the 8 bit word in memory for Read or Write operation.

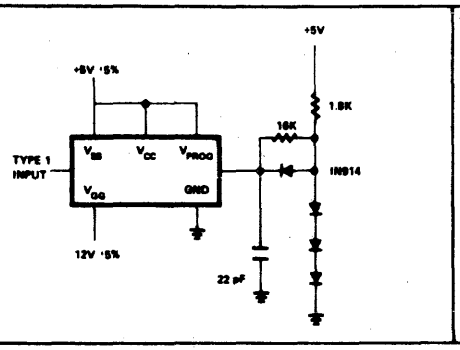
0	0	V_{CC}	Read	Active
1	X	X	Standby	Floating

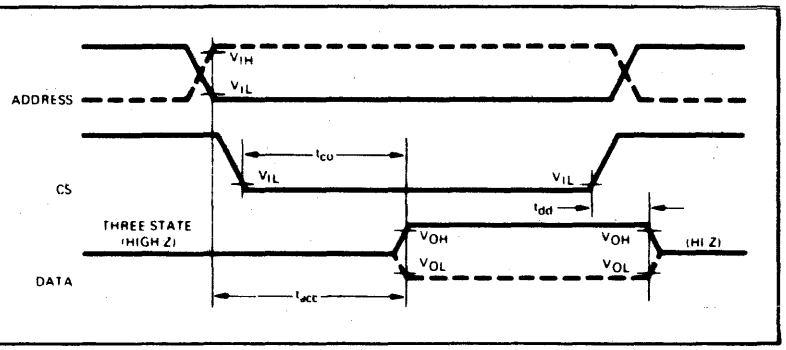
OPERATION

Initially, and after each erasure, all bits of the 5204A are in the LOW state (output 0 volts). Data is stored by selectively programming a HIGH into the desired bit locations. The R/W input (pin 2) is used to select the desired mode of operation. When the R/W input is HIGH the chip is in the write enable mode of operation. The outputs (D_0 – D_7) are disabled (floating) with the corresponding pins becoming the data inputs. The word address is selected in the same manner as in the Read mode. Data to be programmed is presented 8 bits in parallel and after the address and data are set up a programming pulse (V_P = - 50 volts) is applied. V_{PROG} electrically writes the data into the memory array. Writing may be inhibited by deselecting the chip with the CS input at a HIGH during the write cycle. This feature allows true "on board" programming in bus organized systems where the R/W and V_{PROG} inputs are common and the device to be programmed is selected by means of the chip select input as during read operations.



The amount of program energy required to insure memory retention may be defined as a function of the number of program pulses (N) times the program pulse width (t_{pw}) ($N \times t_{pw} \geq 60$ msec). This means if a 3 ms pulse is used, 20 program pulses are required, and if a 5 ms pulse is used 12 program pulses are required.

The read operation is accomplished by a LOW at the R/W input with the program input connected to V_{SS} potential. True data (data out = date in) is valid after the address is stable. The CS input will disable (float) the outputs when HIGH to allow capability with bus organized systems.



Erasure is accomplished by exposing the array to a 2537Å ultra-violet light source (such as Ultra-Violet Products, Inc. Lamp Model S52 or UVS-54, Turner Designs PROM Eraser, Model 30 or equivalent) for a period of 7 to 10 minutes. The clear optical lid should be approximately one inch away from the lamp tubes.

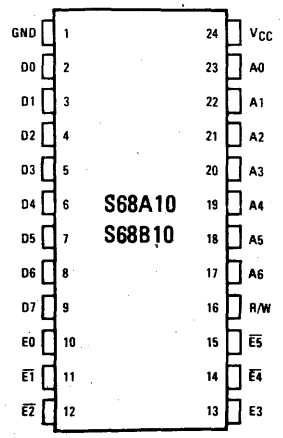
1024 Bit (128×8) Static Read/Write Memory

Features

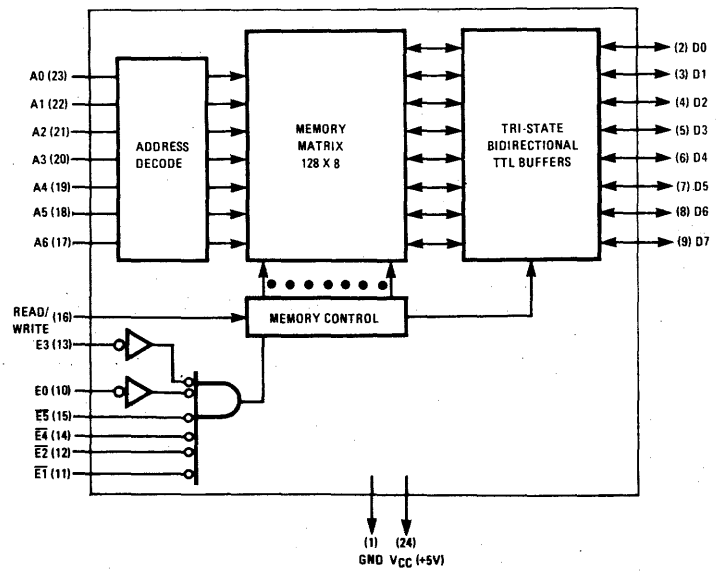
- ☐ Organized as 128 Bytes of 8 Bits
- ☐ Static Operation
- ☐ Bidirectional Three-State Data Input/Output
- ☐ Six Chip Enable Inputs (Four Active Low, Two Active High)
- ☐ Single 5 Volt Power Supply
- ☐ TTL Compatible
- ☐ Maximum Access Time:
  —360ns for S68A10
  —250ns for S68B10

General Description



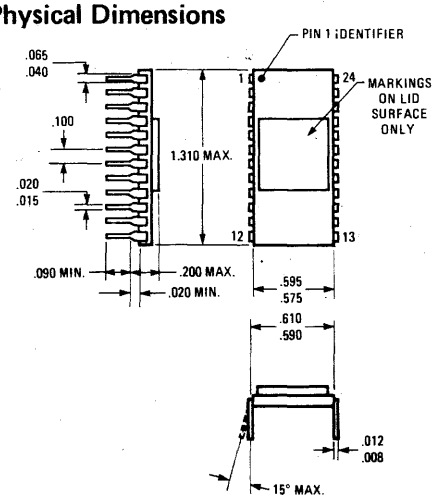
The S68A10 and S68B10 are static 128x8 Read/Write Memories designed and organized to be compatible with the S68A00 and S68B00 Microprocessors. Interfacing to the S68A10 and S68B10 consists of an 8-bit bidirectional data bus, seven address lines, a single Read/Write control line, and six chip enable lines, four negative and two positive.

For ease of use, the S68A10 and S68B10 are a totally static memory requiring no clocks or cell refresh. The S68A10 and S68B10 are fabricated with N-channel silicon gate depletion load technology to be fully DTL/TTL compatible with only a single +5 volt power supply required.



Absolute Maximum Ratings

Supply Voltage	-0.3V to +7.0V
Input Voltage	-0.3V to +7.0V
Operating Temperature Range	0°C to +70°C
Storage Temperature Range	-55°C to +150°C



Pin Configuration

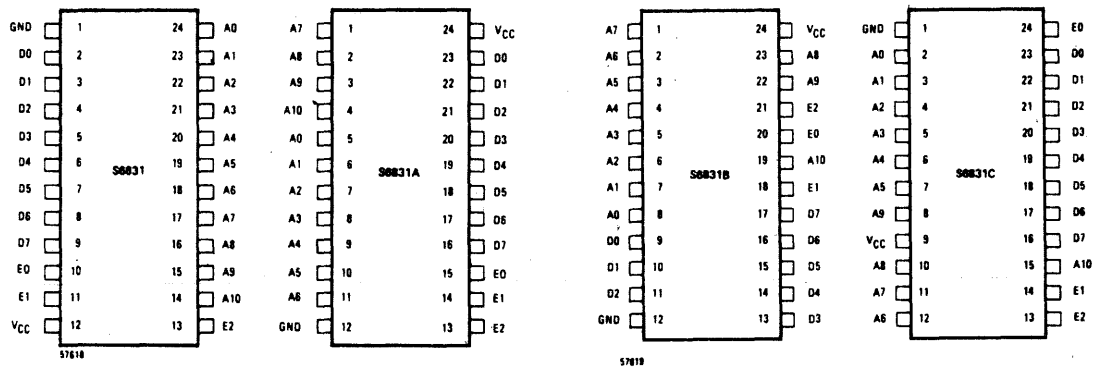
16,384 Bit (2048×8) ROM



ADVANCED PRODUCT DESCRIPTION

BLOCK DIAGRAM

PIN/PACKAGE CONFIGURATION

- Maximum Access Time = 450 ns @ C_L = 130 pF
- Low Power 150 mW avg.
- Organized as 2048-Bytes of 8 Bits
- Static Operation
- Three-State Data Output
- 3 Chip Enable Inputs (Mask Programmable)
- The S6831 is pinout similar with the S6830
- The S6831A is pinout compatible with the 2316A, 8316A
- The S6831B is pinout compatible with the Intel 2316B, MC68317
- The S6831C is pinout compatible with the EA4600
- Single 5-Volt Power Supply
- TTL Compatible Input/Output

FUNCTIONAL DESCRIPTION

The S6831/A/B/C is a 16,384 bit Read Only Memory organized 2K words x 8 bits. This ROM has been designed to supply large bit storage, high performance memory for microprocessors and other demanding applications with simple interface requirements. The device will operate from a single +5V supply and is manufactured with a N-channel silicon gate depletion load technology. This device is available in all common high density ROM pinouts.

ABSOLUTE MAXIMUM RATINGS (See Note 1)

Supply Voltage V_{CC}	- 0.5 to + 7.0V	Operating Temperature Range T_A	0 to + 70°C
Input Voltage V_{in}	- 0.5 to + 7.0V	Storage Temperature Range T_{stg}	- 55 to + 150°C

NOTE 1 Permanent device damage may occur if ABSOLUTE MAXIMUM RATINGS are exceeded. Functional operation should be restricted to RECOMMENDED OPERATING CONDITIONS. Exposure to higher than recommended voltages for extended periods of time could affect device reliability.

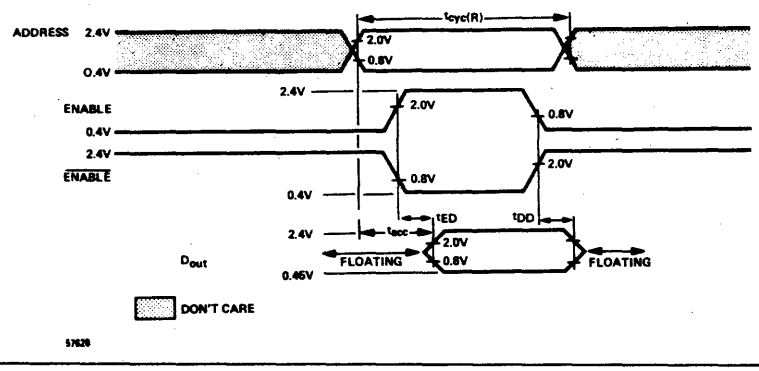
©IC MASTER 1978

DC (STATIC) CHARACTERISTICS (V_{CC} = + 5 Volt ± 5%; T_A = 0°C to + 70°C)

RECOMMENDED DC OPERATING CONDITIONS

Symbol	Parameter	Min.	Typ.	Max.	Unit	Conditions
V_{IH}	Input High Voltage (Norm. Op. Levels)	2.0	–	5.25	Vdc	
V_{IL}	Input Low Voltage (Norm. Op. Levels)	- 0.5	–	0.8	Vdc	
I_I	Input Current (V_I = 0 to 5.25 V)	–	–	2.5	μAdc	
V_{OH}	Output High Voltage (I_{OH} =-100μA)	2.4	–	–	Vdc	
V_{OL}	Output Low Voltage (I_{OL} = 2.1 mA)	–	–	0.4	Vdc	
I_{LOH}	Output Leakage Current (V_O = 2.4, $\overline{E}$ = 0.4V, E = 2.4V)	–	–	10	μAdc	
I_{LOL}	Output Leakage Current (V_O = 0.4V, $\overline{E}$ = 0.4V, E = 2.4V)	–	–	10	μAdc	
I_{CC}	Supply Current (V_{CC} = 5.25V, T_A = 0°C)	–	30		mAdc	

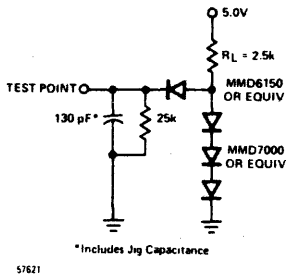
CAPACITANCE



Symbol	Characteristic	Min.	Typ.	Max	Unit	Conditions
C_{in}	Input Capacitance	–	–	7.5	pF	f = 1.0 MHz
C_{out}	Output Capacitance	–	–	10	pF	T_A = 25°C

AC (DYNAMIC) CHARACTERISTICS V_{CC} = + 5 Volt ± 5%; T_A = 0°C to + 70°C

READ CYCLE (All timing with $t_r = t_f$ = 20 ns, Load of Figure 1)



Symbol	Characteristic	Min.	Max.	Unit
t_{cyc} (R)	Read Cycle Time	450	–	ns
t_{ED}	Output Enable Delay Time	–	200	ns
t_{DD}	Output Disable Delay Time	10	150	ns
t_{ACC}	Read Access Time	–	450	ns

READ CYCLE TIMING

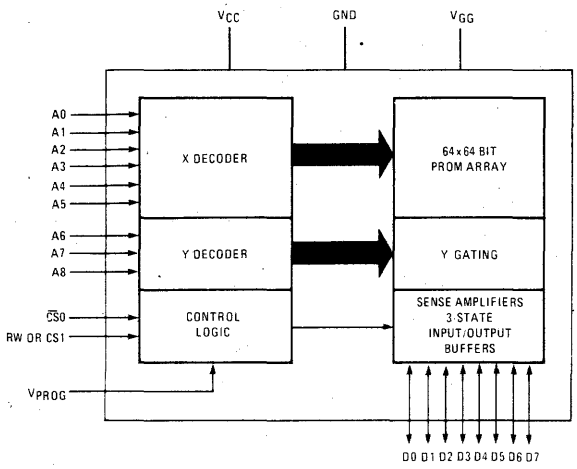
FIGURE 1 – AC TEST LOAD

CUSTOM PROGRAMMING

The preferred method of pattern submission is the AMI Hex format as described below with its built-in address space mapping and error checking. This is the format produced by the AMI Assembler/Loader. The format is as follows and may be on paper tape, punched card or other media readable by AMI.

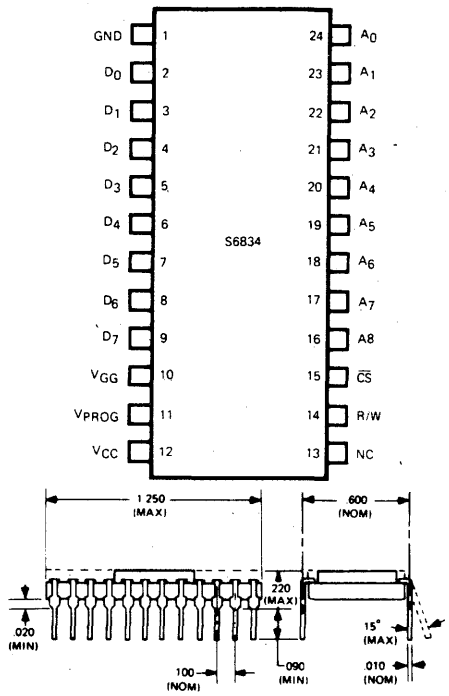
ASCII Character	Description
1	**Start of record** (S)
2	**Type of record** 0 – Header record 1 – Data record 9 – End of file record
3 – 4	**Byte Count** Since each data byte is represented as two hex characters, the byte count must be multiplied by two fo get the number of characters to the end of the record. (This includes checksum and address data.) Records may be of any length being defined in each record by the byte count.
5, 6, 7, 8	**Address Value** The memory location where this record is to be stored.
9, . . . , N	**Data** Each data byte is represented by two hex characters. Most significant character first.
N + 1, N + 2	**Checksum** The one's complement of the additive summation (without carry) of the data bytes, the address, and the byte count.

AMI will accept the input format used for the EA4600 or for the Intel 8316A or B in addition to the above format.



EXAMPLE:

```
S 1 1 3 0 0 0 0 4 9 E 9 F 1 0 3 2 0 F 0 4 9 3 1 3 9 F 7 2 0 0 0 F 5 E 0 F 0 0 1 1 D
S 9 0 3 0 0 0 0 F C



S — START OF RECORD
1 — TYPE OF RECORD
13 — BYTE COUNT (HEX)
0000 — START ADDRESS
49E9F10320F04931 39F72000F5E0F00 — DATA
1D — CHECK SUM
```

4096 Bit (512×8) Erasable and Electrically Reprogrammable ROM

BLOCK DIAGRAM

PIN/PACKAGE CONFIGURATION

FEATURES

- On-Board Programmability
- Fast Access Time – 500 ns Typ.
- Pin Configuration Similar to the S6830 1K x 8 Bit ROM
- High Speed Programming – Less than 1 Minute for all 4096 Bits
- Programmed with R/W, CS and V_{PROG} Pins
- Completely TTL Compatible – Excluding the V_{PROG} Pin during Read and Write
- Ultraviolet Light Erasable – Less than 10 Minutes
- Static Operation – No Clocks Required
- Three-State Data I/O
- Standard Power Supplies +5V and –12V
- Mature P-Chan Process

FUNCTIONAL DESCRIPTION

The S6834 is a high speed, static, 512 x 8 bit, eraseable and electrically programmable read only memory designed for use in bus-organized systems. Both input and output are TTL compatable during both read and write modes. Packaged in a 24 pin hermetically sealed dual in-line package the bit pattern can be erased by exposing the chip to an ultra-violet light source through the transparent lid, after which a new pattern can be written.

TYPICAL APPLICATIONS

- ROM Program Debugging
- Code Translation
- Microprogramming
- Look-up Tables
- Random Logic Replacement
- Programmable Waveforms
- Character Generation
- Electronic Keyboards

©IC MASTER 1978

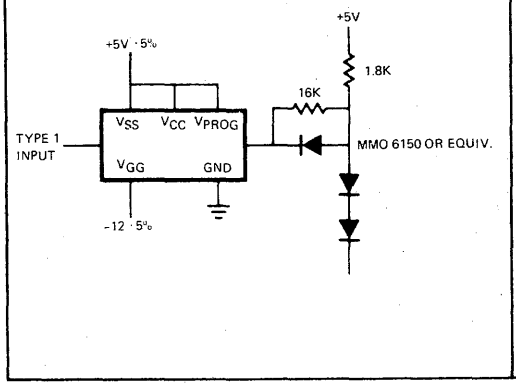
ABSOLUTE MAXIMUM RATINGS

Voltage on any pin relative to V_{SS} except the V_{PROG} pin	+0.3 to −20V
Voltage on the V_{PROG} pin relative to V_{SS}	+0.3 to −55V
Operating Temperature	0°C to +70°C
Storage Temperature (programmed)	−55°C to +85°C
Storage Temperature (unprogrammed)	−55°C to 150°C

NOTE: This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields, however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high-impedance circuit.

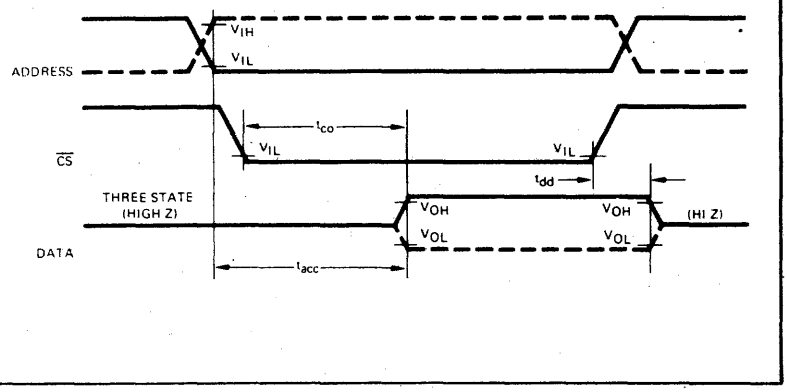
DC (STATIC) CHARACTERISTICS (V_{CC} = +5.0V ± 5%, V_{GG} = −12.0V ± 5% T_A = 0 − 70°C unless otherwise noted).

SYMBOL	CHARACTERISTIC	MIN	MAX	UNIT
V_{IL}	INPUT VOLTAGE LOW		0.8	V
V_{IH}	INPUT VOLTAGE HIGH	V_{CC} −2.25	V_{CC} to .3	V
V_{OL}	OUTPUT VOLTAGE LOW I_{OL} = 1.6 ma		0.4	V
V_{OH}	OUTPUT VOLTAGE HIGH I_{OH} = 200μA	2.4		V
I_{LI}	INPUT LEAKAGE CURRENT		10	μa
I_{LO}	OUTPUT LEAKAGE CURRENT CS = 5V		20	μa
I_{GG}	V_{GG} SUPPLY CURRENT		45	ma
I_{CC}	V_{CC} SUPPLY CURRENT		50	ma
P_D	POWER DISSIPATION		750	mw



NOTE: Program input V_{PROG} may be tied to V_{CC} during the Read.

AC (DYNAMIC) CHARACTERISTICS (Loading is as shown in Figure 1 unless otherwise noted).



SYMBOL	CHARACTERISTIC	MIN	MAX (6834)	MAX (6834−1)	UNIT
T_{ACC}	ACCESS TIME		575	750	ns
T_{CO}	CHIP SELECT TO OUTPUT DELAY		300	400	ns
T_{DD}	CHIP DESELECT TO OUTPUT DELAY		250	325	ns

OPERATION

Initially, and after each erasure, all bits of the 6834 are in the logic "0" state (output 0 volts). Data is stored by selectively programming a logic "1" into the desired bit locations. The R/W input (pin 14) is used to select the desired mode of operation. When the R/W input is at logic "0" the chip is in the write enable mode of operation. The outputs (0_1 –0_8) are disabled (floating) with the corresponding pins becoming the data inputs ($0_1 \rightarrow D_{IN\ 1}$ etc.). The word address is selected in the same manner as in the read mode. Data to be programmed are presented 8 bits in parallel and after the address and data are set up a programming pulse (V_P –50 volts) is applied. V_{PROG} electrically writes the data into the memory array. Writing may be inhibited by deselecting the chip with the CS input at a logic "1" during the write cycle. This feature allows true "on board" programming in bus organized systems where the R/W and V_{PROG} inputs are common and the device to be programmed is selected by means of the chip select input as during read operations.

The amount of program energy required to insure memory retention may be defined as a function of the number of program pulses (N) times the program pulse width (t_{pw}) ($N \times t_{pw} \geqslant 60$ msec). This means if a 3 ms pulse is used, 20 program pulses are required, and if a 5 ms pulse is used 12 program pulses are required.

The read operation is accomplished by a logic "1" at the R/W input with the program input connected to V_{SS} potential. True data (data out = data in) is valid after the address is stable. The CS input will disable (float) the outputs when at a logic "1" to allow or tie capability.

Erasure is accomplished by exposing the array to a high intensity ultra-violet light source (such as, Ultra-Violet Products, Inc. Lamp Model S52 or UVS-54) for a period of 7 to 10 minutes. The clear optical lid should be approximately one inch away from the lamp tubes.

INTERFACE DESCRIPTION

Pin	Label	Function
(2)	D0	**Data Lines** – with the R/W line selected for Read (V_{IH}), the Data Lines (D0 through D7) are set to reflect the contents of the selected memory location. When the R/W line is set for Write (V_{IL}), the Data Lines are input to the addressed location of the 6834 when V_{PROG} is present. The Data Bus output drivers are three-state devices that remain in the high impedance (off) state when CS is in the V_{IH} state of when R/W is in the V_{IL} state.
(3)	D1	
(4)	D2	
(5)	D3	
(6)	D4	
(7)	D5	
(8)	D6	
(9)	D7	
(14)	R/W	**Read/Write** – When this input line is set to V_{IH}, the device is in the Read mode, a low (V_{IL}) signal puts it into the Write mode.
(15)	CS	**Chip Select** – This input line must be set to V_{IL} for a Read or Write operation to be performed. When it is High (V_{IH}) the output data bus is set to a high-impedance three-state condition and disables the Write operation.
(11)	V_{PROG}	**Program** – In the Write mode, a programming pulse (–50V dc) at this input causes the data at the Data Lines to be stored in the selected address. This pin should be tied to V_{CC} for normal Read operations.
(24)	A0	**Address Lines** – These lines select the 8 bit word in memory for Read or Write operation

SEMI 4801 450NSEC, STATIC, TTL IN/OUT 4096x1 N-MOS RAM
SEMI 4804 450NSEC, STATIC, TTL IN/OUT 1024x4 N-MOS RAM

FEATURES

- Single +5V Power Supply
- Replaces 4 1024x1 Static RAMs
- Completely Static— No Clocks or Refresh
- 18 Pin Package
- Access/Cycle Times As Low As 400 nsec max
- 250 mw Typical Operating Power
- TTL Compatible I/O
- Three State Outputs

PIN CONFIGURATION

PRELIMINARY SPECIFICATION

EMM SEMI

8K STATIC N-MOS RAM

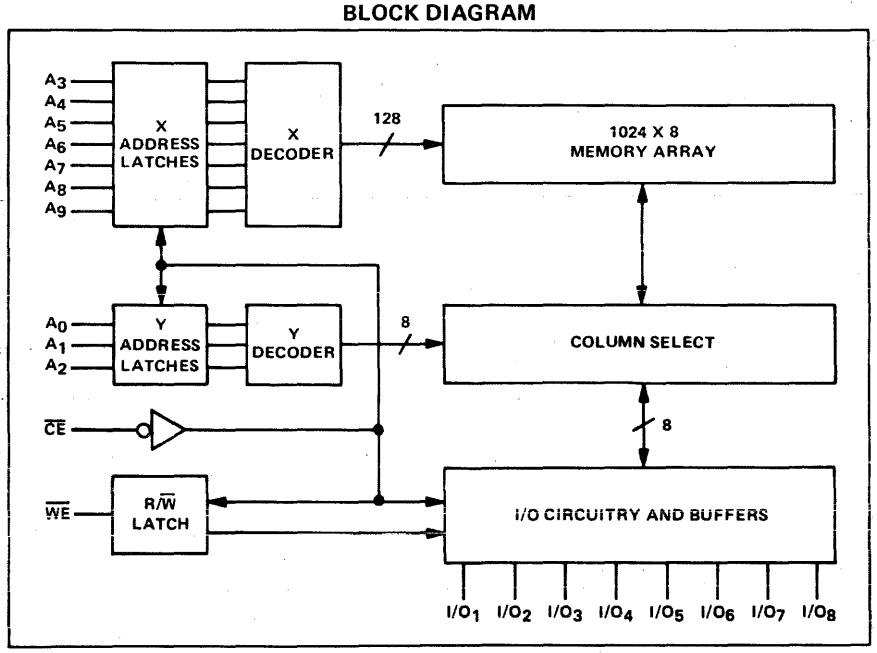
8108 8308

1024 X 8, 300 ns, TTL In/Out

GENERAL DESCRIPTION

EMM SEMI part numbers 8108/8308 are 8192-bit static RAMS, ideally suited for microprocessor applications. The 8108/8308 have common data input/output pins for connection to a data bus. They require only a single +5 volt power supply, and are TTL compatible on all inputs and outputs. These devices also have a low power disabled mode which dissipates less than 60 mW power.

FUNCTIONAL DESCRIPTION



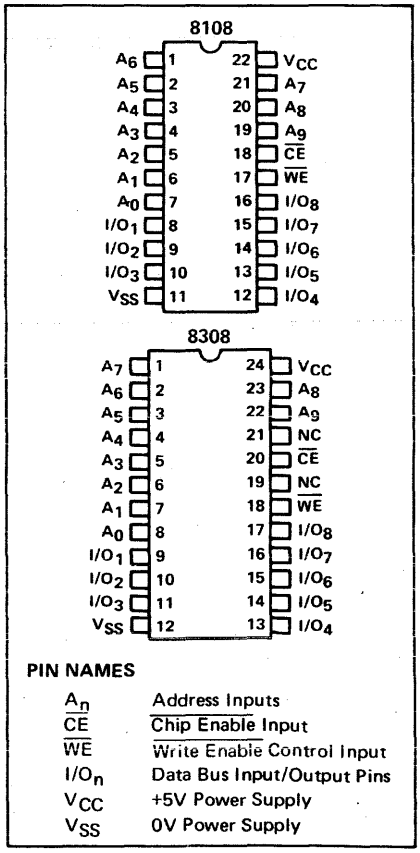
The EMM SEMI 8108/8308 are 8192-bit static RAMS with memory cells organized in eight arrays of 128 rows by 8 columns (1024 words X 8 bits). Each eight-bit word is addressed by simultaneously decoding the X addresses (A_3 through A_9) for the rows, and the Y addresses (A_0 through A_2) for the columns. Data is written or read in parallel on eight common input/output pins (I/O_n). The operation of the 8108/8308 is controlled by Chip Enable ($\overline{CE}$) and Write Enable ($\overline{WE}$).

When $\overline{CE}$ is high, all outputs are in an inoperative high impedance state, and power is supplied only to the memory elements. When $\overline{CE}$ is low, the memory is enabled for reading and writing.

The negative going edge of $\overline{CE}$ begins timing for a read cycle. Data on $\overline{WE}$ and address pins(A_n) must be stable for time T_H. $\overline{WE}$ and A_n will then have been latched into "D" type flip flops and no longer need to be held stable. Output data will be presented on the eight output pins (I/O_n) within time T_A and will remain until time T_{DR} after $\overline{CE}$ goes high. Data will then be invalid. After time T_C another read or write cycle can be initiated.

The negative going edge of $\overline{CE}$ also begins timing for a write cycle. $\overline{WE}$ and I/O must be held stable for time T_H. These inputs will then have been latched and I/O will be entered within time T_{CSW}. Another read or write cycle can be initiated after time T_C.

BLOCK DIAGRAM



- 1024 words X 8 bits
- EPROM, PROM, ROM pinout compatible
- Common I/O bus
- Single +5V power supply
- No max. limit on Chip Enable ($\overline{CE}$) pulse width
- 300 nSec maximum access time
- Less than 60 mW power (disabled)
- Less than 270 mW power (enabled)
- Standard 22-pin DIP (8108)
- Standard 24-pin DIP (8308)

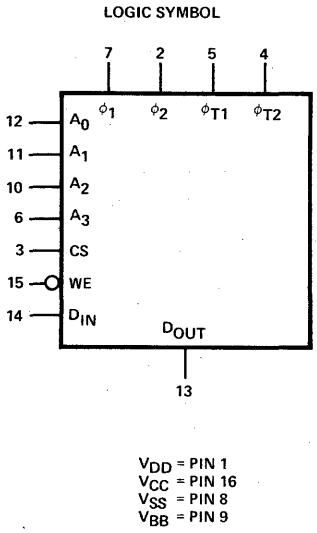
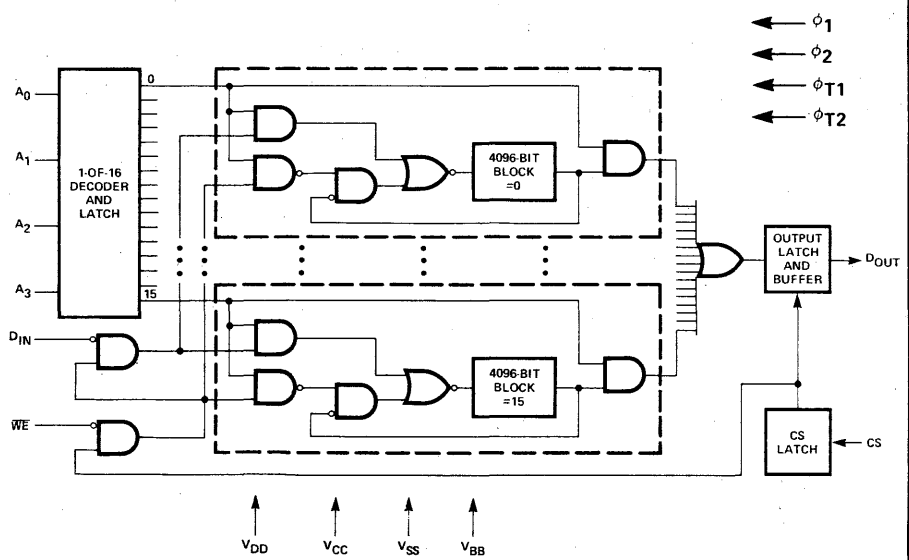
F464

65,536 X 1 DYNAMIC SERIAL MEMORY



FAIRCHILD CHARGE COUPLED DEVICE

GENERAL DESCRIPTION – The F464 is a 65,536-bit dynamic serial memory configured as 16 randomly accessible shift registers, each 4096 bits long. Each of these shift registers is designed utilizing Charge Coupled Device (CCD) techniques with the interlaced Serial-Parallel-Serial (SPS) register structure which features both low power and high density characteristics. The high density of the F464 is further enhanced through the use of an electrode-per-bit memory cell approach. The high density permits packaging the memory in a standard 16-pin (0.3"-wide) dual in-line package which allows the construction of highly dense memory systems using widely available automated testing and insertion equipment.



Furthermore, this buried-channel CCD memory is fabricated using Fairchild's double-poly n-channel Isoplanar process. This process allows the F464 to be a high performance, state-of-the-art memory circuit which is manufacturable in large volume.

- INDUSTRY STANDARD 16 PIN (0.3"-WIDE) DUAL IN-LINE PACKAGE.
- OPERATING FREQUENCY RANGE: 1 MHz TO 5 MHz.
- 15 μs HALT TIME AT 2.0 MHz
- LOW CAPACITANCE TTL-COMPATIBLE INPUTS (EXCEPT CLOCKS).
- 3-STATE, TTL-COMPATIBLE, LATCHED DATA OUTPUT.
- OUTPUT DRIVE CAPABILITY: 3.5 mA
- LOW CAPACITANCE 12 V CLOCKS:
  - ϕ_1 AND ϕ_2: 100 pF (TYP)
  - ϕ_{T1} AND ϕ_{T2}: 30 pF (TYP)
- LOW POWER
  - NORMAL OPERATION: <336 mW (MAX) @ f_{max}
  - STANDBY: <66 mW (MAX) @ f_{min}
- STANDARD POWER SUPPLIES (+12 V, +5 V, AND –5 V)

FUNCTIONAL DESCRIPTION

ORGANIZATION – The F464 is a 65,536 x 1 bit dynamic serial memory organized internally as 16 dynamic shift registers (or blocks) of 4096 bits each in length. These 16 shift register blocks are randomly accessible through four internally decoded Address inputs (A_0 – A_3). When a given register is selected, its input and output are internally connected (as needed) to the D_{IN} and D_{OUT} pins, respectively, thus permitting simultaneous read and write operations.

ARCHITECTURE – Each of the sixteen shift register blocks is implemented using a Serial-Parallel-Serial (SPS) register architecture. In this approach N data bits are sequentially shifted into a "serial" input register. When full, the entire N-bit word is shifted in parallel into N "parallel" registers of M bits in length, as illustrated in Figure 1. At the other end of this parallel register structure, bits are loaded in parallel into an N-bit serial output register. Bits in this register are then shifted out toward the sense amplifier at the output and are automatically recirculated back to the input serial register unless a WRITE operation is specified.

The primary advantages of this type of architecture include very high density, low power, and low clock capacitance. These features all result from the fact that in the SPS architecture the parallel registers which encompass most of the total storage capacity within each block are shifted at a considerably slower rate (f_{IN}/N) than the clock rate of the input or output serial registers (f_{IN}).

In actuality, each 4096-bit block of the F464 is implemented using an "interlaced" SPS structure in which each bit of the input serial register services two parallel registers rather than just one. The same is true for the output serial register. In addition, "electrode-per-bit" design techniques are used to reduce the effective cell size by minimizing the number of electrodes used to store each bit of information. These techniques obviously enhance the memory density considerably. The dimensions of the F464's interlaced SPS structure are 32-bit input and output serial registers and 64 parallel registers, each 63 bits in length. See Figure 2. These dimensions were chosen in order to optimize the power/density/latency tradeoffs inherent in the CCD memory approach.

CLOCKS – The F464 requires four MOS level clocks: two high frequency (1 to 5 MHz) serial clocks and two low frequency transfer clocks. The serial clocks, ϕ_1 and ϕ_2, control the movement of data within the input and output serial registers of each 4096-bit block and have a frequency equal to the data rate. The transfer clock ϕ_{T1} is used to transfer data from the input serial register to the parallel registers while the transfer clock ϕ_{T2} is used to transfer data from the parallel registers to the output serial register of each block. The data present in the parallel registers is shifted by internally generated ripple clocks. This ripple clock technique allows a high bit-packing density approaching one electrode per bit.

To achieve proper transfer phasing, the two transfer clocks are asymetrical about a 32-cycle interval (31.5 and 32.5 cycles) but symmetrical about a 64-cycle interval. The phasing between these transfer clocks alternates in order to achieve correct bit storage in each block. When ϕ_{T1} occurs during ϕ_1 time, ϕ_{T2} occurs during ϕ_2 time 1.5 cycles prior to ϕ_{T1}. When ϕ_{T1} occurs during ϕ_2 time, ϕ_{T2} occurs during ϕ_1 time 2.5 cycles prior to ϕ_{T1}. Figure 3 illustrates the clock phase relationships.

The clocking operation may be momentarily halted for as long as 15 μs once each interval of 64 or more clock cycles provided that the clock frequency is at least 2.0 MHz or higher. During this "halt time" it is recommended that all clock signals be in the LOW state in order to limit power dissipation.

CONTROLS

In addition to the four Address inputs (A_0 through A_3), other TTL level control signals available on the F464 include Write Enable ($\overline{WE}$) and Chip Select (CS). The CS input, along with the address information, is presented during ϕ_1 HIGH time and dynamically latched with the trailing edge of ϕ_1 which simultaneously disables both the address and CS buffers. This action prevents changes that occur on the external pins from entering the internal circuitry when ϕ_1 is LOW. The $\overline{WE}$ control signal determines whether new data from the D_{IN} pin, or recirculated output data, is presented to the input of the addressed block. The non-addressed blocks are automatically recirculated.

MODES OF OPERATION

STANDBY (Recirculate-only cycle)

In Standby mode (CS LOW), the contents of all 16 blocks are recirculated automatically, and the device disregards the $\overline{WE}$, Address, and D_{IN} inputs. The output latch goes into the high impedance state after the trailing edge of the ϕ_1 clock. Minimum power dissipation results when the device is operated in the recirculate mode with minimum ϕ_1 and ϕ_2 pulse widths at the lowest allowed frequency.

READ-RECIRCULATE MODE

In this mode of operation ($\overline{WE}$ HIGH and CS HIGH) the data from the selected block is presented to the output buffer immediately following the leading edge of ϕ_2 and appears at the output, D_{OUT}, after a delay equal to the access time t_{ACC}. Thus, the access time is referenced from the leading edge of the ϕ_2 pulse and is independent of the duration of ϕ_2. The output data is latched and remains valid at the D_{OUT} pin until the end of the ϕ_1 clock pulse in the next cycle. The data present in all 16 blocks automatically recirculates from the output back to the input regardless of the address inputs, provided that $\overline{WE}$ remains inactive throughout the cycle.

READ AND WRITE MODE

In the Read and Write mode ($\overline{WE}$ LOW and CS HIGH), the output data from the selected block is available at the output pin as in the read-recirculate mode; however, the recirculate path of that particular block is disabled. Input data present at the D_{IN} pin during ϕ_2 is written into the selected block by the falling edge of ϕ_2, while the other 15 blocks automatically recirculate their contents. This form of an "early-write" cycle ($\overline{WE}$ LOW prior to the falling edge of ϕ_1) requires that both $\overline{WE}$ and D_{IN} have set-up times with respect to the trailing edge of ϕ_1. In fact, for successive write operations handled in this mode, $\overline{WE}$ may be held LOW continuously without returning it to the HIGH state between cycles. A "delayed-write" cycle ($\overline{WE}$ goes LOW after the trailing edge of the ϕ_1 clock pulse) is also possible and is discussed in the next paragraph as a subset of the RMW operating mode.

READ-MODIFY-WRITE MODE

The Read-Modify-Write mode (CS HIGH, $\overline{WE}$ HIGH goes LOW) is simplified by the fact that the F464 is always in the read mode whenever it is selected (CS HIGH). Since the access time is referenced to the leading edge of ϕ_2 and the setup times of $\overline{WE}$ and D_{IN} are referenced to the trailing edge of ϕ_2, this mode of operation requires an extended ϕ_2 HIGH time in order to provide the required modify time. This "stretched" ϕ_2 HIGH time may be determined by the following relationship:

$$t_{\phi 2H} = t_{ACC} + t_{MOD} + t_{DS} + t_{WCL} + t_T$$

The modify time, t_{MOD}, is determined by the user and is dependent on the delays of the external logic used to modify the output data. The Read-Modify-Write (RMW) cycle time then, is given by:

$$t_{CYC} = t_{\phi 1H} + t_{UL1} + t_{\phi 2H} + t_{UL2} + 4t_{TC}$$

where $t_{\phi 2H}$ is the new "stretched" version of the ϕ_2 clock pulse.

If no modification of output data is required, then this operating mode reduces to a "delayed-write" mode in which D_{IN} and $\overline{WE}$ may occur after the ϕ_1 clock pulse.

©IC MASTER 1978

MEMORY START-UP

When the F464 is initially powered up, the V_{BB} supply (i.e., the –5 volt supply) should be applied to the memory before and removed after the other supplies. This action results in greater protection against accidental violation of the voltage limits specified in the Absolute Maximum Ratings section and, in general, enhances the long term reliability of the memory.

In order to clear the memory of extraneous charge following power-up or after a clock stoppage of greater than 15 μs, the F464 must be clocked through a minimum of 20,000 clock cycles of any type before a valid memory cycle should be attempted.

ABSOLUTE MAXIMUM RATINGS

Voltage of any pin relative to V_{BB} ($V_{SS} - V_{BB} \geqslant 4.5$ V)	–0.5 V to +20 V
Operating Temperature (Ambient)	0°C to 55°C
Storage Temperature (Ambient)	–55°C to 150°C
Power Dissipation	1 W

Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

DC REQUIREMENTS: $T_A = 0°C$ to $55°C$ (See Note 1)

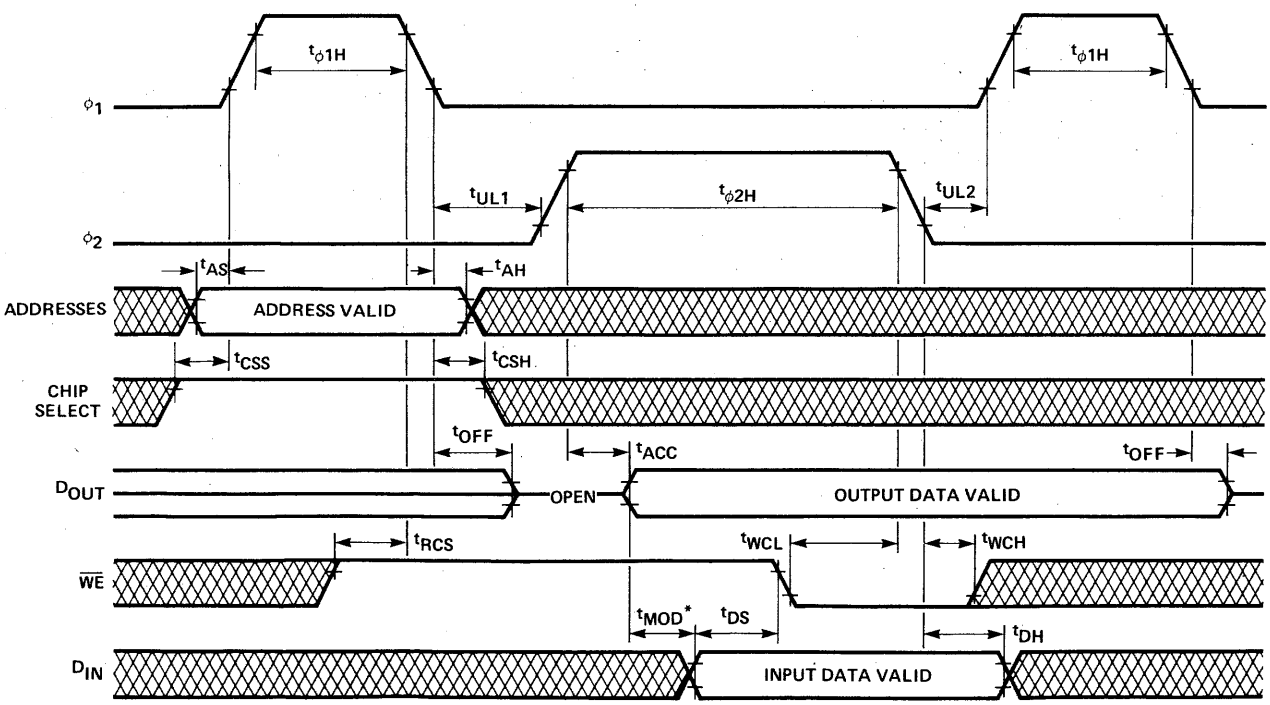
NOTES:



1. All voltages are measured with respect to V_{SS}.
2. The differential voltage between a LOW for any clock input and a LOW for any other clock input should not exceed 0.8 V.
3. Current levels at both minimum and maximum frequencies are specified for minimum ϕ_1 and ϕ_2 clock pulse widths. See Figure 4.
4. Measured at maximum frequency and $V_{BB} = -5.5$ V.
5. Measured with $I_{OUT} = -2.5$ mA.
6. Measured with $I_{OUT} = 3.5$ mA.
7. Input leakage current is measured with $V_{IN} = V_{DD}$ for clock inputs and $V_{IN} = V_{CC}$ for all other inputs.
8. Leakage current at the D_{OUT} pin is measured for both V_{OUT} equal to V_{CC} and V_{SS} when the output buffer is in the high impedance state.
9. Effective capacitance is calculated from the equation $C = I\ \Delta t/\Delta V$ with $\Delta V = 12$ V for clock inputs and with $\Delta V = 3$ V for TTL pins while the device is active. Measured parameters are current and time.
10. Maximum clock pulse widths are specified in order to limit power dissipation. See Figure 4 showing the relationship between power and clock pulse width.
11. Reference levels used for timing measurements are V_{IHC} (min) and V_{ILC} (max) for clock inputs and V_{IH} (min) and V_{IL} (max) for all other inputs. Transition times for both rise and fall are measured between these reference points.
12. Minimum and maximum frequency values assume clock transition times of 10 ns.
13. The Read-Recirculate command is performed by keeping $\overline{WE}$ in the inactive state (i.e. HIGH) for the prescribed set-up and hold times.
14. t_{DS} references D_{IN} to the trailing edge of ϕ_1 in a Read-(early) Write cycle. However, in a Read-Modify Write (i.e. delayed write) cycle, t_{DS} references D_{IN} to the negative-going edge of $\overline{WE}$.
15. t_{OFF} (max) defines the time at which the output achieves the open circuit condition and is not referenced to output voltage levels.
16. Measured with a load equivalent to two TTL loads and 100 pF. See Fig. 5.
17. The clocking operation maybe momentarily halted for as long as 15 μs once each interval of 64 or more clock cycles provided that the clock frequency is at least 2.0 MHz or higher. During this "halt time" it is recommended that all clock signals be in the LOW state in order to limit power dissipation.

CLOCK GENERATION CIRCUIT –

The circuit shown below may be used to generate the four MOS-level clocks required of the F464 from a single master clock. In this circuit, the master clock frequency f, must be twice the desired data rate at the F464 output pin. Since the input clock frequency is "squared-up" with a divide-by-two flip-flop, the duty cycle of this clock is non-critical. A pulse edge at the input of the buffered delay line produces a sequence of delayed pulse edges from the A, B, C, D and E output taps. These delayed pulse edges are ANDed together to produce the required ϕ_1 and ϕ_2 clocks as well as the ϕ_{T1} and ϕ_{T2} transfer clocks. Since the transfer clocks occur in a symmetrical fashion every 64 clock cycles, a 6-bit, modulo 64 counter is required. The outputs of this 6-bit counter are decoded to enable the appropriate transfer clock gates at counts of 29, 31, 61 and 63. Thus, ϕ_{T1} is passed along to the clock drivers only during cycles 31 and 63, while ϕ_{T2} is gated through only during cycles 29 and 61. These four counts are easily decoded with only a 2-to-4 decoder and one 4-input NAND gate. The 6 bits of the modulo 64 counter comprise the 6 low order bits of the 12-bit, modulo 4096 loop counter. This counter is required to define address locations within each 4K block and will, in most cases, be already present in the system.

One major advantage of using a delay line is that since the clock pulses are generated from delayed edges, the pulse width in all cases is fixed and does not vary as a function of the input master frequency f. Thus minimum pulse widths are always generated regardless of cycle and data rates. This translates directly into lower power dissipation since I_{DD} is a function of clock pulse width.

The maximum clock rates for which this circuit will operate properly depends on the clock transition times (both rise and fall) at the output of the TTL-to-MOS drivers and, the delay between adjacent taps on the delay line. The maximum data rates possible for this circuit are given in the table. Faster and/or more efficient clock generation circuits may be realized by using different types of delay lines (e.g. more taps or unequal tap delays).

SERIAL AND TRANSFER CLOCK GENERATION CIRCUIT

DELAY LINE TOTAL DELAY	TAP DELAY	RISE / FALL TIME	MAX. DATA RATE
100 ns	20 ns	10 ns	4.0 MHz
125 ns	25 ns	10 ns	3.0 MHz
150 ns	30 ns	15 ns	2.75 MHz
200 ns	40 ns	20 ns	1.0 MHz

BOTH THE 5 MHz F464A AND THE 4 MHz F464 WILL WORK FOR ALL THE CASES ABOVE WITH THE ONLY EXCEPTION BEING THE F464 IN THE CASE OF THE 100 ns DELAY LINE.

Fairchild cannot assume responsibility for use of any circuitry described other than circuitry entirely embodied in a Fairchild product. No other circuit patent licenses are implied.

READ MODE: AC ELECTRICAL CHARACTERISTICS

SYMBOL	PARAMETER (See Note 8)	F2708-1		F2708		UNITS	NOTES
		MIN	MAX	MIN	MAX		
t_{ACC}	Address to Output Delay Time		350		450	ns	
t_{CSO}	Chip Select to Output Delay Time		120		120	ns	
t_{OFF}	Chip Deselect to Output High Impedance		120		120	ns	
t_{DA}	Data Valid After Address Time	0		0		ns	

NOTES:

1. All voltage levels are referenced to V_{SS} = 0 V.
2. Worst case supply currents occur when all inputs are HIGH (including $\overline{CS}$/WE = 5.0 V) and the ambient temperature is T_A = 0°C.
3. Measured both with V_{IN} = 5.25 V and V_{IN} = V_{IL} (min) = V_{SS}.
4. Measured both with V_{OUT} = 5.25 V and $\overline{CS}$/WE = 5.0 V.
5. The total power dissipation of the 2708 is specified at 800 mW. It is not calculable by summing the various currents (I_{DD}, I_{CC} and I_{BB}) multiplied by their respective voltages, since current paths exist between the various power supplies and V_{SS}. The I_{DD}, I_{CC} and I_{BB} currents should be used to determine power supply capacity only.
6. Measured with V_{IN} = 0 V, T_A = 25°C and f = 1.0 MHz.
7. Measured with V_{OUT} = 0 V, T_A = 25°C and f = 1.0 MHz.
8. Timing parameters are measured with input logic levels of V_{IL} (max) = 0.65 V and V_{IH} (min) = 3.0 V. Timing measurement reference levels are 0.8 V and 2.8 V for inputs and 0.8 V and 2.4 V for outputs. An output load of 1 TTL gate plus 100 pF is assumed.

READ MODE TIMING DIAGRAM

PROGRAMMING INSTRUCTIONS

After the completion of an ERASE operation, every memory cell in the F2708 is in the logic "1" state (as indicated by a HIGH level at the data outputs). An 8-bit byte of data is entered into the memory by programming logic "0"s into the appropriate cell locations at some given address. Word locations in the memory are addressed in the same way as in READ operations. Once a cell is programmed to a logic "0", it can only be altered through ultraviolet light erasure.

In order to program the F2708, the $\overline{CS}$/WE input must first be set to 12 V. Data to be programmed is entered in 8-bit bytes through the output data terminals (Q_0 through Q_7). Input logic levels for the data lines, addresses, and supply voltages are the same as in a READ operation.

Programming is accomplished by executing a number (N) of passes through a programming loop, each of which involves sequencing through all 1024 locations in the address space. In each pass through the loop, a single, high voltage (26 V) pulse is applied to the PRGM input, once at each address. Logic "0"s applied to the data pins (Q_0 through Q_7) are written into the proper bit positions at the location specified by the address inputs (A_0 through A_7). There must be N successive passes through the programming loop in order to guarantee reliable programming of information. The required number of loops (N) is a function of the pulse width (t_{PW}) of the high voltage programming pulse applied to the PRGM input. Total programming time is given by the relationship:

$$t_{TOTAL} = N \times t_{PW} \geq 100 \text{ ms} \quad (1)$$

©IC MASTER 1978

The allowed range of pulse widths is from 0.1 ms to 1.0 ms. This implies that the minimum value of N must be in the range of 100 to 1000. WARNING: Applying more than one programming pulse in succession to the same address is not permitted since it will result in damage to the device. At the end of a program sequence, the $\overline{CS}$/WE falling edge transition must occur before the first address transition when changing from the PROGRAM mode to the READ mode. The PRGM pin should be pulled down to approximately V_{SS} (i.e., ground) with an low impedance device since this pin sources several milliamps of current when $\overline{CS}$/WE is at 12 V and the PRGM pin is LOW.

PROGRAMMING EXAMPLES

The programming relationship in Equation 1 above should always be used in determining values of t_{PW} and N.

Example 1 The full capacity of 1024 bytes could be programmed using 0.2 ms programming pulse widths. In this case, the minimum number of passes through the programming loop would be

$$N = \frac{t_{TOTAL}}{t_{PW}} = \frac{100\ ms}{0.2\ ms} = 500\ loops. \quad (2)$$

Each of the 500 programming loops must sequence through address locations 0 through 1023.

Example 2 Word locations 0 to 200 and 300 to 700 are to be programmed. All other bits are "don't cares". The programmed pulses are 0.5 ms wide. Thus, the minimum number of program loops is

$$N = \frac{100\ ms}{0.5\ ms} = 200\ loops. \quad (3)$$

The data entered into the "don't care" locations should consist of all logic "1"s. Even though portions of the address space are not used (or "don't cares"), the programming loop should still sequence through all 1024 addresses on each pass.

Example 3 Extending the case of Example 2, the F2708 is now to be updated to include new data at locations 850 to 880 which previously were programmed as "don't cares"; in this case, logic "1"s. The minimum number or programming loops is the same as in Example 2, N = 200 loops. Address locations 0 to 200 and 300 to 700 must be reprogrammed with their original data pattern. The remaining unused addresses should again be programmed as logic "1"s.

ERASING INSTRUCTIONS

The contents of the F2708 EPROM can be erased by exposure to high intensity shortwave ultraviolet (UV) light with a wavelength of 2537 Angstroms (Å). This can be accomplished with ultraviolet light EPROM erasure devices which are available from several U.S. manufacturers. These erasure devices contain a UV light source which is usually placed approximately one or two inches from the EPROM such that the transparent window on top of the device is illuminated. The minimum required integrated dose (intensity x exposure time) of UV light energy incident on the window of the device in order to reliably insure complete erasure is 12.5 Watt-sec/cm^2. The UV erasure unit should be periodically calibrated if minimum exposure times are to be used. (Minimum exposure times range from 10 to 45 minutes, depending on model type and age of UV lamp). If longer exposure times are possible, variations in the output light intensity of the UV light source are not critical.

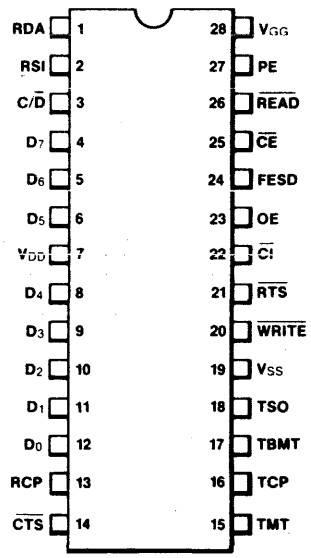
3843 USART

UNIVERSAL SYNCHRONOUS OR ASYNCHRONOUS RECEIVER AND TRANSMITTER

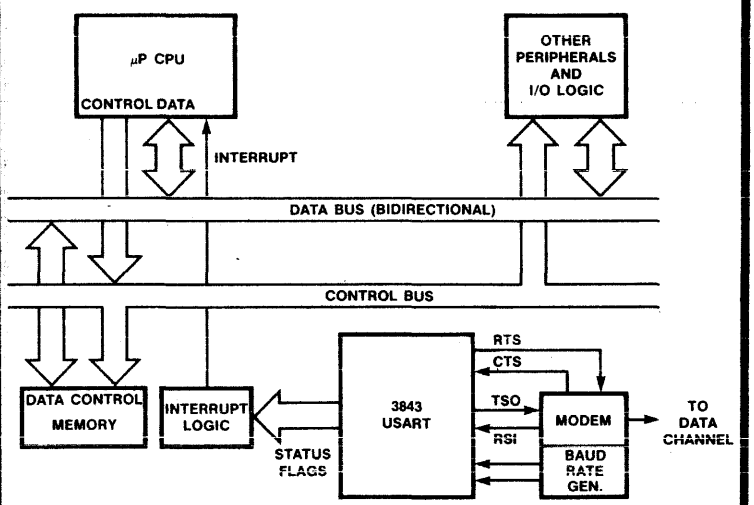
FAIRCHILD ISOPLANAR SILICON GATE NMOS

GENERAL DESCRIPTION—The 3843 is a programmable, full duplex Universal Synchronous or Asynchronous Receiver and Transmitter (USART) designed for use in data communications systems. This device provides the interface between the bus-oriented format of the controller and the serial format of the peripheral unit. The programming inputs of the USART determine the transmission mode, character length, framing format, parity mode and baud rate.



The 3843 is manufactured with the n-channel Isoplanar silicon gate process, and is available in both plastic and ceramic 28-pin dual in line package as well as in commercial and military temperature ranges.

- 5, 6, 7, or 8-BIT SELECTABLE CHARACTER LENGTH
- ODD OR EVEN PARITY GENERATION AND CHECKING
- SELECTABLE NUMBER OF STOP BITS (1, 1½, 2) IN ASYNCHRONOUS MODE
- SEPARATE RECEIVER AND TRANSMITTER CLOCKS
- SELECTABLE CLOCK RATES (16x, 32x, or 64x BAUD RATES)
- STATIC OPERATION—NO MINIMUM FREQUENCY
- MAXIMUM BAUD RATES: (3843-1DC)



1x CLOCK (SYNC MODE)	-	320K BAUD
16x CLOCK (ASYNC MODE)	-	20K BAUD
32x CLOCK (ASYNC MODE)	-	10K BAUD
64x CLOCK (ASYNC MODE)	-	5K BAUD

- ERROR FLAGS: OVERRUN, PARITY, AND FRAMING ERRORS
- HARDWARE AND SOFTWARE STATUS FLAGS FOR BOTH RECEIVER AND TRANSMITTER STATUS
- DOUBLE BUFFERED, FULL DUPLEX OPERATION
- EXTERNAL OR INTERNAL (ONE OR TWO SYNC WORDS) SYNCHRONIZATION
- TTL COMPATIBLE INPUTS AND OUTPUTS
- 3-STATE DATA BUS WITH OR-TIE CAPABILITY

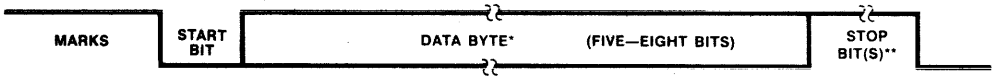
BLOCK DIAGRAM



FUNCTIONAL DESCRIPTION

The 3843 USART is a programmable interface device designed for use in CPU-controlled digital data communications applications where parallel-to-serial and serial-to-parallel conversions of digital data are required. In a typical communications system, the USART converts output data from the processor which is formatted in a parallel fashion, into serially formatted data for transmission over a data channel. At the same time, it also converts incoming serial data into parallel formatted bytes of data for use by the processor. The 3843 also inserts bits (async mode) or characters (sync mode) into the serial data stream as dictated by the particular transmission format employed, and then strips them from the data stream during reception. Thus, the USART is a transparent interface which the CPU recognizes simply as an I/O port for bytes of data: the USART handling the reformatting and transmission/reception of data thereby freeing the CPU from this time consuming task. The operational mode of the USART is definable by the CPU software through a sequence of control instructions which completely specify USART functions. (See the Programming Section for details). One of the items specified in the format type which is either synchronous or asynchronous. The following sections provide a general discussion of the 3843's operating modes.

Transmitter Operation: Asynchronous Mode

To transmit data in the asynchronous operating mode the CPU places a byte of data on the data bus and then inputs it into the USART with a strobe pulse on the $\overline{WRITE}$ pin. If the C/$\overline{D}$ (Control or Data) input is HIGH, then the word is loaded into either the Mode Register, one of the Sync Registers, or the Command Register, depending on the current location in the programming sequence. (See the Programming Section). If the C/$\overline{D}$ input is LOW, then the information on the data bus will be loaded into the Transmitter Buffer Register. This register serves as temporary storage for the next data character to be transmitted. The Transmitter Register, on the other hand, contains the data character currently being transmitted. The bits in this register are serially shifted out through the TSO (Transmitter Serial Output) pin as a serial bit stream. When the Transmitter Register become empty, the next word to be transmitted is loaded into this register from the Transmitter Buffer. When this happens, the buffer becomes empty and the TBMT (Transmitter Buffer Empty) status flag is set HIGH. If both the transmitter and the transmitter buffer registers becomes empty then the TMT (Transmitter Empty) status flag is set HIGH. These and other status flags are available as output pins as well as through the status word which can be monitored by the system software.

In the asynchronous format "framing bits are appended to the data character to be transmitted before it is output via the TSO pin. Prior to the sending of actual data bits, a "start-bit" (a logic "0") is inserted before the data to signify the beginning of a character. See Figure 1.

*Variable byte size is defined in the Mode Instruction with unused bits being set to logic "0".

**Either one, one and one half, or two STOP bits as prescribed in the Mode Instruction.

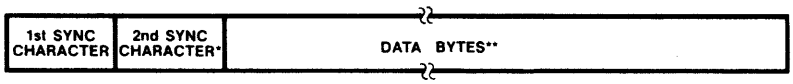


FIG. 1 ASYNCHRONOUS TRANSMISSION/RECEPTION FORMAT

The data character itself may consist of a byte of from five to eight bits in length. This length must be specified by the Mode Instruction prior to transmission. This same instruction also indicates if an optional parity bit should be automatically inserted after the data and whether it should be even or odd. Following the parity bit are the "stop-bits" (logic "1"s) of which there may be one, and one-half, or two. These stop bits indicate the end of the transmitted data character. Each bit is output for an interval of time (referred to as one "bit-time") which is either 16, 32, or 64 clock pulses in length as specified by the Mode Instruction. These clock pulses are input via the TCP (Transmitter Clock Input) pin.

The entire assembly of bits, including START, parity, and STOP bits, is then shifted out through the TSO output as a serial bit stream provided that a logic "1" has been programmed into the TE (Transmitter Enable) bit of the command register. If there is a pause in transmission, the TSO output is forced into the inactive state until the CPU initiates further transmissions. In its inactive state the TSO output is normally HIGH and is said to be in the "marking" state, or sending "marks" continuously.

Transmitter Operation: Synchronous Mode

Transmission of serial data in the synchronous mode is accomplished by transmitting entire blocks of five, six, seven, or eight-bit bytes of data, one after another in a serial data stream, with no framing bits added between bytes. Synchronizing information is supplied with either one or two "sync-characters" which must precede each block of data *(See Figure 2)*.

*The use of an optional second SYNC Character is specified in the Mode Instruction.

**There is no inherent limitation on the number of bytes in the data block.

FIG. 2 SYNCHRONOUS TRANSMISSION/RECEPTION FORMAT

Data presented to the USART from the CPU via the data bus is handled in exactly the same manner as in the previously described asynchronous mode except for the addition of sync-characters between the Mode and Command Instructions. While in the synchronous mode, if the C/D pin is HIGH following the Mode Instruction, then the next word will be interpreted as the first of possibly two sync characters and is loaded into the appropriate register. (See the Block Diagram on page 2). The second sync character (if used) is handled similarly and is loaded into a second sync-word register. These sync characters are output to the TSO pin whenever the transmitter register becomes empty. In this way synchronization is not lost but rather is maintained by the USART automatically transmitting sync words as "sync-fill" characters until the CPU loads a new byte of data. After a Master Reset has been programmed, the TSO output ceases to transmit sync characters and goes to a continuous HIGH state.

Receiver Operation: Asynchronous Mode

Data is received in the async mode from the modem on the RSI (Receiver Serial Input) line. This line, which is normally HIGH, is taken LOW by the reception of a START bit which signals the USART that incoming data is imminent. Through the use of the Mode Instruction, the USART has been programmed to accept a serial data stream with bit times of either 16, 32, or 64 clock periods in length. (Each bit of data lasts for either 16, 32, or 64 pulses of the receiver clock input, RCP). The falling edge of the START bit is used as a reference by an internal clock pulse counter that allows the USART to sample the RSI input at the chronological center or midpoint of each bit time. Incoming bits are reassembled in the Receiver Register where the START, STOP, and parity bits are stripped from the receiver data. The parity bit (if it is used) is recomputed and compared against the received parity bit with the PE (Parity Error) flag being set accordingly. An internal bit counter counts off the expected number of data bits along with a possible parity bit and assumes that any additional bits are stop bits. If any of

©IC MASTER 1978

the anticipated number (either one, one and one-half, or two) of STOP bits is detected as a logic "0", then the FE (Framing Error) flag will be set. When the reassembled data character is transferred to the Receiver Buffer Register, the USART then signals the CPU that received data is available for fetching by taking the RDA (Receiver Data Available) line HIGH. The CPU responds by driving the $\overline{READ}$ input LOW which causes the data word to appear on the USART's data bus. Should the CPU fail to read the data word before the next received character is transferred into the receiver buffer, then the previous character is written over by the new character and the OE (Overrun Error) flag is set.

The occurrence of either a parity error, a framing error, or an overrun error does not necessarily preclude other USART operations from continuing. All of the error flags may be reset via the MR bit of the command instruction.

Receiver Operation: Synchronous Mode

Data which is received in the synchronous mode may consist of many bytes of data in one block. If the 3843 is programmed for operation in the internal sync mode, then the incoming block of data must be prefaced with either one or two sync characters. When the RE (Receiver Enable) bit of the command instruction is programmed to a logic "1", the USART begins loading serial bits input via the RSI pin into the Receiver Register. This register is continuously compared on a bit basis to the first sync character until a match occurs. If two sync characters are being used, the next byte is compared to the second sync character and if a match condition occurs, then the USART is properly synchronized for receiving data. If a match condition does not exist for the second sync character, then the USART resumes searching for another occurrence of the first sync character. Once the USART receiver is synchronized, it will remain so until the Receiver Enable bit is reset to a logic "0" or until the EH (Enter Hunt Mode) bit of the command instruction is programmed to a logic "I". The EH command causes the receiver to stop transferring data to the Data Bus until the receiver acquires proper synchronization again.

Reception of data can also be accomplished in the external synchronization mode. This is done by using the FESD pin as an external sync input and taking it HIGH during the second bit of the first non-sync or data word in the block.

PIN DEFINITIONS

The inputs and outputs of the 3843 can be categorized by function since some signals are intended for use between the USART and the CPU, while other signals link the USART to the data channel. Those input and output signals of the 3843 associated with the CPU are:

Chip Initialize	($\overline{CI}$)
Chip Enable	($\overline{CE}$)
Control/Data	($\overline{C/D}$)
Read	($\overline{READ}$)
Write	($\overline{WRITE}$)
Data Bus	($D_0 - D_7$)
Receiver Data Available	(RDA)
Transmitter Buffer Empty	(TBMT)
Transmitter Empty	(TMT)
Framing Error/SYNC Detected	(FESD)
Parity Error	(PE)
Overrun Error	(OE)

The last six of these signals are hardware status signals used by the CPU to monitor USART activity. Since these six signals also appear in the Status Word, they may be read by the software as well as by the hardware. Those input and output signals of the 3843 associated with the channel are:

Request To Send	($\overline{RTS}$)
Clear To Send	($\overline{CTS}$)
Receiver Serial Input	(RSI)
Transmitter Serial Output	(TSO)
Receiver Clock	(RCP)
Transmitter Clock	(TCP)

The functional significance of each of these signals is discussed in the following sections.

Chip Initialize ($\overline{CI}$) – This initialization signal will hold the USART in a reset state as long as it remains LOW. When $\overline{CI}$ goes HIGH, the proper sequence of mode instructions must be executed in order to program the USART for operation (See the programming section).

©IC MASTER 1978

Chip Enable ($\overline{CE}$) – This signal enables the USART so that its data bus I/O buffer will respond when a Read or Write Control signal occurs. $\overline{CE}$ does not affect other USART activity when it goes HIGH, but merely prevents any further communication with the CPU and places the data bus I/O buffer in the high impedance state.

Control Data (C/$\overline{D}$) – During a WRITE operation, the 3843 must distinguish command and control information present on its Data Bus from incoming data words. A similar decision must be made during a READ operation to determine if a control status word or a data word should be placed on the Data Bus. In both of these cases, the 3843 distinguishes command, and status information by a HIGH on the C/$\overline{D}$ input pin, while a LOW signifies input/output data.

Read ($\overline{READ}$) – When the CPU supplies a LOW to the 3843's READ input, it causes the USART to output either data (C/$\overline{D}$ = 0) or status (C/$\overline{D}$ = 1) information onto the data bus.

Write ($\overline{WRITE}$) – Instructions or data words placed on the data bus by the CPU are loaded into their respective registers within the 3843 whenever the CPU places a LOW on this input.

Receiver Data Available (RDA) – This signal goes HIGH when there is received data present in the internal receiver register of the 3843 and is used to signal the CPU that it may read the data word from the USART.

Data Bus (D_0 — D_7) – The data bus consists of eight bi-directional lines which connect the CPU and the USART. The bus is used to send both data and command words from the CPU to the USART. It also allows the USART to send received data and status flag information back to the CPU.

Parity Error (PE) – The PE flag is set whenever a parity error is detected by the receiver. It may be reset by programming the Error Reset (ER) bit of the command instruction. The occurence of a parity error does not necessarily preclude other USART operations from continuing and may be handled as desired by the designer. Parity error indication when parity has not been selected is invalid.

Overrun Error (OE) – In the receiving mode, the overrun error flag is set whenever the CPU does not read a character before the next one becomes available. It is reset by programming the Error Reset (ER) bit of the command instruction word. The occurence of an OE does not preclude further USART operations, however the previously overrun character is lost.

Transmitter Buffer Empty (TBMT) – The Transmitter Buffer is an internal register which contains the next character to be transmitted. The TBMT status flag indicates when this buffer becomes empty after its contents have been loaded into the Transmitter Register. The CPU monitors this status flag and may load a new word into the buffer when TBMT goes HIGH.

Transmitter Empty (TMT) – The TMT status flag is a signal which indicates to the CPU whenever both the Transmitter and Transmitter Buffer Registers are empty. When this happens, the USART will automatically start transmitting "sync-fill' characters if in the sync mode or "marks" if in the async mode.

Framing Error/Sync Detected (FESD) – This pin is multi-functional and is used only during reception of serial data from the channel. It functions as a Framing Error output flag during asynchronous operation and a Sync-Detected flag during synchronous operation. It is also the external "sync-found" input for external sync operation.

When receiving data from the channel in the synchronous mode, the FESD pin may be either an input or an output, depending upon whether the USART was programmed for internal or external synchronization. If programmed for internal synchronization, the FESD pin will act as an output indicating that the last character received matched the previously programmed internal sync character, and character assembly will be initiated on the next non-sync character. If programmed for external synchronization, then, the FESD pin will be used as a sync-detected input.

Request To Send ($\overline{RTS}$) – This output signal is activated by programming the TE (Transmitter Enable) bit of the command instruction word and is used to signal the modem that the USART is ready to transmit data.

Clear To Send ($\overline{CTS}$) – This signal is generated by the modem in response to an RTS command and indicates to the USART that the channel is now ready to accept data. Internally, the $\overline{CTS}$ enables the transmitter register to output serial data to the channel via the TSO pin provided that the Transmitter Enable (TE) bit of the command word was set.

Receiver Serial Input (RSI) – Input serial data from the channel is presented to the USART on its RSI pin. Data present on the RSI pin is entered into the internal receiver register of the 3843 at a rate and format as specified by the mode instruction and the receiver clock frequency.

Transmitter Serial Output (TSO) – The TSO output of the USART supplies the serial data to be transmitted by the channel. Data bits stored in the Transmitter Buffer are output, via the TSO, at a rate and format as specified by the Mode Instruction and the transmitter clock frequency.

©IC MASTER 1978

Receiver Clock (RCP) – This clock signal controls the rate at which the serial data is received from the channel. In the synchronous receiving mode the clock frequency is equal to the actual baud rate (1x); while in the asynchronous mode the clock frequency is either 16, 32, or 64 times the actual baud rate as prescribed in the Mode Instruction.

Transmitter Clock (TCP) – This clock controls the rate at which serial data is transmitted to the channel. In the synchronous transmission mode, the clock frequency is equal to the actual baud rate (1x); while in the asynchronous mode the clock frequency is either 16, 32, or 64 times the actual baud rate as prescribed in the Mode Instruction.

PROGRAMMING THE USART

Prior to commencing data transmission or reception the 3843 must be programmed for operation in the desired mode. The CPU accomplishes this programming by writing into the 3843, via the data bus, a sequence of specific instruction words which represent a complete functional description of the type of communications format the USART is to use. These instruction words are

1) the Mode Instruction,
2) either zero, one, or two sync characters (depending on the mode selected)
3) the Command Instruction.

This instruction sequence must follow either a pulse on the $\overline{CI}$ (Chip Initialize) pin or a Master Reset command.

The Mode Instruction is the first one in the programming sequence and specifies the details of the operational format. The significance of each bit of the instruction word is described in Table 1.

In the synchronous format—internal sync mode, the Mode Instruction is followed immediately in the programming sequence by either one or two sync characters, depending on whether single or double sync word operation was called for in the previous Mode Instruction. These characters need not be specified and may be omitted if the 3843 was programmed for either the asynchronous mode or the external sync mode.

The last instruction in this sequence is the Command Instruction. Following the SYNC character(s), this instruction controls certain internal operations and status conditions within the USART. The significance of the bits in this instruction word is shown in Table 2. All control words presented to the USART (C/D = 1) after this instruction will also be considered as Command Instructions until a command word indicating a Master Reset is performed. An example is shown in Figure 4.

Status Flags – The status flags of the 3843 collectively form a status word which can be read by the CPU program software. This is accomplished by taking both the $\overline{READ}$ and $\overline{CE}$ lines LOW and the C/$\overline{D}$ line HIGH. The format of the status word is:

D_0	D_1	D_2	D_3	D_4	D_5	D_6	D_7
TBMT	RDA	TMT	PE	OE	FESD	CTS	

These flags have the same meaning as their corresponding output pins and are reset in the same way. See the Pin Definitions section.

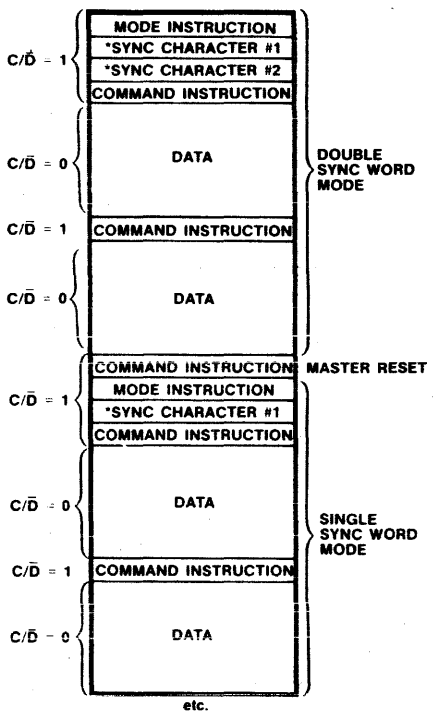
TABLE 2 COMMAND INSTRUCTION WORD

D_0	RE	D_2	D_3	D_4	D_5	D_6	D_7
TE	D_1	EH	SB	ER	SDR	MR	

TE = Transmitter Enable — A "1" programmed in this bit holds the USART in the transmission mode and activates the RTS pin. The transmitter will be enabled after $\overline{CTS}$ goes LOW.

RE = Receiver Enable — A "1" in this bit enables the USART to receive and assemble characters input via the RSI pin.



EH = Enter Hunt Mode — A "1" in this bit will cause the USART to "search" for SYNC characters when in the SYNC mode. It is a don't care in ASYNC mode operation. This command is self-cancelling after sync is achieved.

SB = Send Break Character — When programmed to a "1", this bit causes the TSO output line to go LOW continuously until this bit is reset to "0" with another Command Instruction.

ER = Error Reset — A "1" in this bit will reset the PE, OE, and FE (when in ASYNC mode) pins. This command is self-cancelling.

SDR = Sync Detect Reset — A "1" in this bit will reset the FESD pin (when in the internal SYNC mode). This command is self-cancelling.

MR = Master Reset — A "1" in this bit will hold the USART in a reset mode. This bit is equivalent to the $\overline{CI}$ pin. The Master Reset command is self-cancelling.

A programming example showing the sequence of data ($C/\overline{D} = 0$) and control instructions ($C/\overline{D} = 1$) presented to the USART via the data bus is shown at left. The initializing sequence consists of Mode and Command Instructions and either zero, one, or two sync characters depending on what type of format is called for in the Mode Instruction. (No sync characters are used in the async mode or the external sync mode). Any instructions received after a Mode Instruction (except for sync characters) are considered to be a Command Instruction unless a Master Reset command precedes them. The example shows how the USART's operating format may be altered under program control if desired. It applies to both transmission and reception of data in either the synchronous or asynchronous modes.

*May or may not be included, depending on the operating mode.

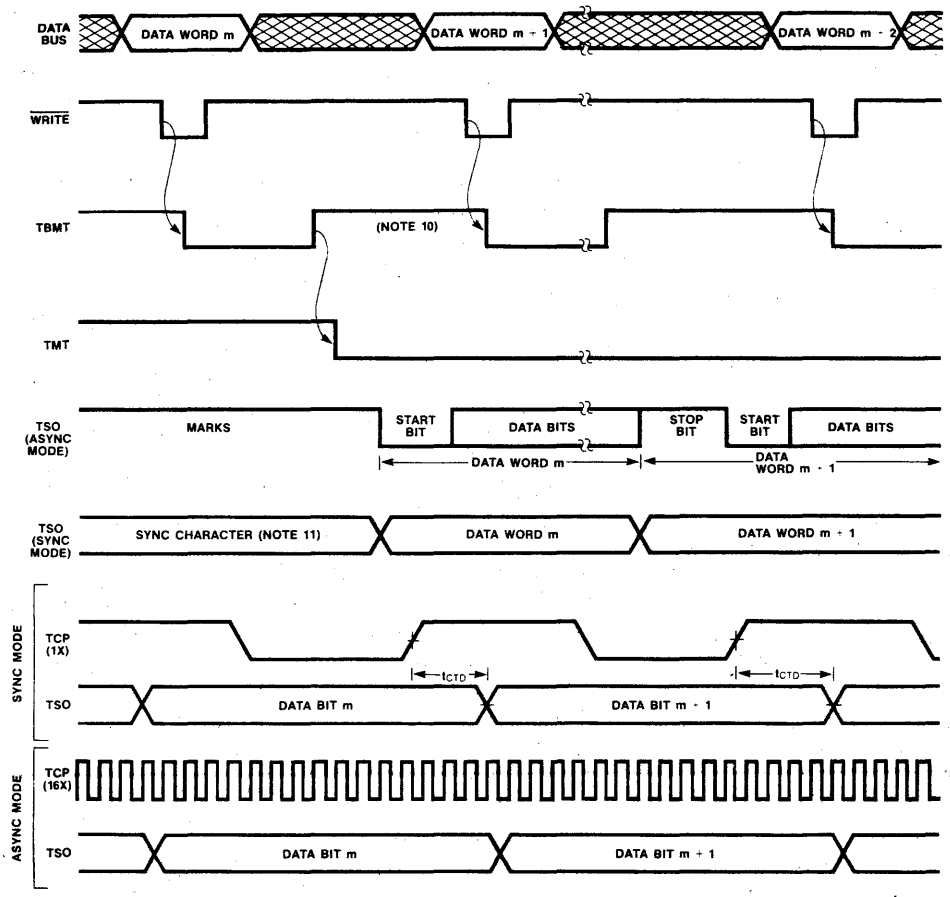
TIMING DIAGRAMS (Cont'd)

RECEIVER TIMING—ASYNC MODE

RECEIVER TIMING—SYNC MODE



NOTES:

1. The minimum allowable time between successive $\overline{\text{WRITE}}$ pulses is given by the parameter t_{SWP} min.
2. The Chip Enable signal and the $\overline{\text{READ}}$ or $\overline{\text{WRITE}}$ signal and ANDed together internally to form an effective $\overline{\text{READ}}$ or $\overline{\text{WRITE}}$ signal. Therefore, the last of these two signals to go LOW in a $\overline{\text{READ}}$ or $\overline{\text{WRITE}}$ operation generates the leading edge of this internal signal while the first to go HIGH generates the trailing edge. It is to the edges of this internal signal that the $\overline{\text{READ}}$ or $\overline{\text{WRITE}}$ timeing parameters are referenced. For purposes of illustration, the timing diagram shows Chip Enable as beginning before and extending beyond the externally applied $\overline{\text{READ}}$ or $\overline{\text{WRITE}}$ signal. Thus, the timing parameters are referenced to $\overline{\text{READ}}$ or $\overline{\text{WRITE}}$ rather than $\overline{\text{CE}}$.
3. The data bus buffer turn-off delay time, i.e. t_{OFF}, is referenced from the rising edge of either $\overline{\text{READ}}$ or $\overline{\text{CE}}$, whichever occurs first. t_{OFF} max defines the time at which the data I/O bus achieves the open circuit high impedance condition and is not referenced to output voltage levels.
4. For purposes of illustration, the transmitter buffer is assumed to be empty prior to the $\overline{\text{WRITE}}$ cycle shown.
5. For purposes of illustration, $\overline{\text{RTS}}$ is shown going LOW, implying that a command instruction ($C/\overline{D} = 1$) is being input with a "0" programmed in the appropriate bit location. See programming instructions.
6. This diagram illustrates the recommended timing relationship between RDA and $\overline{\text{READ}}$. The external system logic responds to RDA by pulsing the $\overline{\text{READ}}$ line. RDA is then reset after $\overline{\text{READ}}$ returns HIGH again, i.e., inactive.
7. This diagram illustrates receiver timing for the 16x async mode. Other modes are similar in operation. Here the START bit is sampled after eight cycles of the RCP clock. The 8-cycle count-off begins with the first negative transition of the RCP clock after the RSI line goes LOW. Subsequent sampling points are separated by intervals of 16 clock periods each.
8. The sync-detected condition is indicated by the FESD pin going HIGH no sooner than three bit times after the reception of the last sync character in the internal sync mode.
9. In the external sync mode, the external decoding of sync characters must be accomplished and the FESD pin forced HIGH indicating synchronization detected during the bit time interval corresponding to the second data bit.
10. The $\overline{\text{WRITE}}$ pulse causes the TBMT flag to be reset. Another cycle should not be attempted until after the TBMT flag has returned HIGH and the t_{SWP} (min) delay time has elapsed. See Note 1.
11. If the double sync character mode is being used, then sync characters will always be transmitted in pairs, and whenever the first is transmitted, the second character will always follow. Therefore transmitted data will always be immediately preceded by the second sync character in this mode.

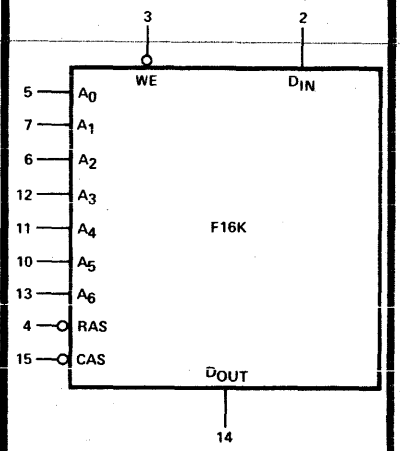
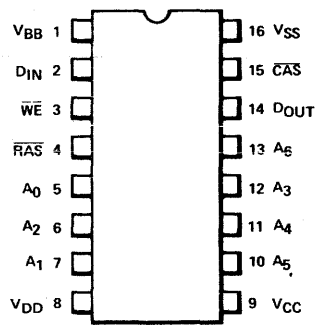
F16K



16,384 x 1 DYNAMIC RANDOM ACCESS MEMORY

FAIRCHILD ISOPLANAR SILICON GATE MOS

GENERAL DESCRIPTION – The F16K is a 16,384-bit MOS Dynamic Random Access Memory configured as 16,384 one-bit words, and which is manufactured using Fairchild's n-channel silicon gate, double-poly Isoplanar process. The use of the single-transistor memory cell along with address multiplexing techniques permits the packaging of the F16K in a standard 16-pin dual in-line package. The use of this package allows construction of highly dense memory systems utilizing widely available automated testing and insertion equipment. Furthermore, the pinout, timing and organizational characteristics of the F16K are essentially the same as Fairchild's 4K dynamic RAMs, the M4027 and the 4096. Thus the F16K is ideally suited for easy upgrading of M4027 or 4096-based systems.



- **INDUSTRY STANDARD 16-PIN DUAL IN-LINE PACKAGE**
- **LOW CAPACITANCE, TTL-COMPATIBLE INPUTS (INCLUDING CLOCKS)**
- **ON-CHIP ADDRESS AND INPUT DATA LATCHES**
- **3-STATE TTL-COMPATIBLE OUTPUT WITH DATA VALID TIME CONTROLLED BY $\overline{CAS}$**
- **COMMON I/O CAPABILITY**
- **TWO DIMENSIONAL SELECTION BY DECODING BOTH $\overline{RAS}$ AND $\overline{CAS}$**
- **STANDARD 10% SUPPLIES (+12 V, +5 V, and –5 V)**
- **FLEXIBLE TIMING WITH PAGE-MODE AND EXTENDED PAGE BOUNDARIES**
- **128-CYCLE $\overline{RAS}$-ONLY REFRESH**
- **PINOUT COMPATIBLE WITH M4027 OR 4096 FOR EASY SYSTEM UPGRADING**

FUNCTIONAL DESCRIPTION

ADDRESSING – The 14 address bits required to decode one-of-16, 384 cell locations in the F16K are entered using a 2-phase multiplexing operation in which first the 7-bit Row Address is entered followed by the 7-bit Column Address. First the 7-bit Row Address is applied to the seven address inputs of the F16K and latched into the chip by Row Address Strobe ($\overline{RAS}$) which is the first of two externally applied TTL-level clocks. The second clock, Column Address Strobe ($\overline{CAS}$), subsequently latches the seven column address bits into the chip. Each of these signals $\overline{RAS}$ and $\overline{CAS}$, trigger on-chip clock generators which control the internal sequencing of events on the chip. Advanced techniques used in handling the row and column address information allow the address multiplexing operation to be performed without lengthening the critical timing path governing the access time. The activation of $\overline{CAS}$ strobes the column address latch but this event as well as other internal events governed by the $\overline{CAS}$ clock generator may be inhibited until certain prerequisite events controlled by the $\overline{RAS}$ clock generator have occured.

More specifically, a "window" of time exists, extending from $t_{RCD(min)}$ to $t_{RCD(max)}$ during which $\overline{CAS}$ may become active without impacting the access time. Stated another way, as long as $\overline{CAS}$ occurs during this window, the access time will be specified by t_{RAC}. If $\overline{CAS}$ occurs a certain delay after this window of time, the $\overline{RAS}$ clock generator no longer inhibits the $\overline{CAS}$ clock generator and the magnitude of this delay will add directly to the overall access time. This lengthened access time is now referenced to $\overline{CAS}$ rather than $\overline{RAS}$ and is lengthened by the amount of time that t_{RCD} exceeds the $t_{RCD(max)}$ limit. This "gated-$\overline{CAS}$" feature allows greater flexibility since the $\overline{CAS}$ clock may be externally activated as soon as the Hold Time for the Row Address has been met and the address inputs have been changed from Row Address to Column Address information.

PAGE MODE OPERATION – The Page-Mode feature of the F16K allows successive memory cycles accessing the same row in the memory matrix to be concatenated together in such a way that the common Row Address need be supplied only once - resulting in faster access times with no corresponding increase in power. The page-mode option may be used in conjunction with any of the defined memory operations, and is accomplished by supplying the Row Address to the chip and holding $\overline{RAS}$ LOW throughout all subsequent memory cycles for which the Row Address is common.

Since $\overline{RAS}$ makes its initial negative transition only once, no additional dynamic power is dissipated due to $\overline{RAS}$ on any subsequent cycles performed within that row. The access and cycle times are also shortened since the time required to supply a Row Address is eliminated.

DATA INPUT – In a write operation, the data to be input into memory is strobed into an on-chip register during $\overline{RAS}$ by a combination of $\overline{CAS}$ and Write Enable ($\overline{WE}$). The strobe is formed by whichever is the latter of these two signals to make its negative transistion. This presents several possibilities in how a write cycle may be performed. In an "early-write" cycle ($\overline{WE}$ active LOW before $\overline{CAS}$ goes LOW), Data In (D_{IN}) is strobed by $\overline{CAS}$ and thus the set-up and hold times are referenced to this signal edge. If D_{IN} is not yet valid at the time $\overline{CAS}$ becomes active (or if the cycle is a read-write or read-modify-write) then $\overline{WE}$ must be delayed. In this delayed-write mode, the D_{IN} set-up and hold times are referenced to $\overline{WE}$ rather than $\overline{CAS}$. (See the timing diagrams).

DATA OUTPUT – The Data Out (D_{OUT}) latch and buffer unconditionally assume the high-impedance state whenever $\overline{CAS}$ is HIGH, i.e. inactive. If the cycle being performed is a read, read-modify-write, or a delayed write cycle then the D_{OUT} latch and buffer will remain high impedance until the access time, after which D_{OUT} will assume the value of the data read from the selected cell. This output data is of the same polarity (not inverted) as the input data and will remain valid as long as $\overline{CAS}$ is kept active, i.e. LOW. However, if the cycle is an "early-write" cycle or if the chip fails to receive both $\overline{RAS}$ and $\overline{CAS}$, then D_{OUT} will remain high impedance throughout the cycle. This feature allows systems which write employing the early write mode exclusively, to common D_{IN} and D_{OUT} directly together.

Another advantage of this "unlatched output" feature is that OR-tied outputs in a memory matrix require no special action to be turned off. Unlike other types of RAMs which require a negative transition of $\overline{CAS}$ to become high impedance, the F16K's output is already high impedance whenever $\overline{CAS}$ is HIGH, i.e. inactive. This means that $\overline{CAS}$ need not be supplied to unused devices and therefore may be used for device selection. Thus a reduction in external decoding logic is possible by using both $\overline{RAS}$ and $\overline{CAS}$ in a 2 dimensional decoding/selection scheme. (see Table 1 below).

$\overline{RAS}$ active during cycle?	$\overline{CAS}$ active during cycle?	RESULT (after t_{OFF} delay)
Yes	Yes	Device active
Yes	No	Device deselected, refresh
No	Yes	Device deselected
No	No	Device deselected

TABLE 1

EXTENDED PAGE BOUNDARY – A further implication of using both $\overline{RAS}$ and $\overline{CAS}$ for device decoding/selection is in extending page boundaries for page-mode operation. If only $\overline{RAS}$ is decoded, then any given "page" is limited to only 128 different column addresses within that page, (i.e. seven column address bits correspond to 2^7 = 128 column addresses). Therefore, for memory systems using more than 16K words of data, page boundaries may be extended from 128 addresses per page up to any multiple of 128 addresses merely by decoding which 16K memory bank also gets a $\overline{CAS}$

©IC MASTER 1978

(subject to $t_{RAS(max)}$ limitation). This is accomplished by supplying $\overline{RAS}$ to all devices in order to latch in the Row Address information and then decoding which bank of 16K words is to also get $\overline{CAS}$. Only those devices which receive both $\overline{RAS}$ and $\overline{CAS}$ will respond with a valid memory cycle.

INPUT/OUTPUT LEVELS – All inputs, including the two address strobes, interface directly with TTL. The high-impedance, low-capacitance input characteristics simplify input driver selection by allowing use of standard logic elements rather than specially designed driver elements. Termination resistors are normally required in a system to prevent ringing due to line inductance and reflections. In high-speed memory systems, transmission line techniques must be employed on the signal lines to achieve optimum system speeds. Series termination may be employed at some degradation of system speed.

The 3-state output buffer is a low impedance to V_{CC} for logic "1" and low impedance to V_{SS} for logic "0". The effective resistance to V_{CC} is 420 Ω maximum and 135 Ω typically. The effective resistance to V_{SS} is 95 Ω maximum and 35 Ω typically.

REFRESH – The matrix of 128 X 128 memory cells in the F16K is refreshed by executing a memory cycle at each of the 128 Row Addresses within each interval of 2 milliseconds or less. Although any cycle in which $\overline{RAS}$ occurs accomplishes a refresh operation, the refresh is most easily accomplished in the $\overline{RAS}$-only-refresh mode. This type of refresh operation results in decreased power dissipation since $\overline{CAS}$ remains inactive.

POWER DISSIPATION/STANDBY – Since the F16K uses dynamic memory cells, this means that most of the dissipated power is a result of an address strobe edge. There is, however, a small dc component of dissipated power that is associated with the precharging of the sense amplifiers. Thus, the total power dissipated is a function of both operating frequency and duty cycle. Typically, the power is 350 mW at 1 μs cycle time with a worst case power of less than 462 mW at 375 μs cycle time. To reduce overall system power during standby, $\overline{RAS}$-only-refresh cycles should be performed with $\overline{CAS}$ held HIGH.

The V_{CC} supply is not used in the internal memory operations of the F16K, but rather used only at the output buffer and thus, for some applications, may be powered from the supply voltage of the logic to which the chip's output is interfaced. This means that I_{CC}, the current drawn from the V_{CC} supply, is a function of output loading. During battery standby operation, the V_{CC} pin may be unpowered, if desired, without affecting the refresh operation. This allows all system logic, except the $\overline{RAS}$ timing circuitry and the refresh address logic, to be turned off during battery standby to conserve power.

PIN NAMES

A_n	Address Inputs	D_{OUT}	Data Output
D_{IN}	Data Input	V_{CC}	+5 V Power Supply
$\overline{WE}$	Write Enable Input (Active LOW)	V_{SS}	0 V Power Supply
$\overline{RAS}$	Row Address Strobe (Clock) Input (Active LOW)	V_{BB}	–5 V Power Supply
$\overline{CAS}$	Column Address Strobe (Clock) Input (Active LOW)	V_{DD}	+12 V Power Supply

ABSOLUTE MAXIMUM RATINGS

Voltage of any pin relative to V_{BB} ($V_{SS} - V_{BB} \geq 4.5$ V)	–0.5 V to + 20 V
Operating Temperature (Ambient)	0°C to 70°C
Storage Temperature (Ambient)	–55°C to 150°C
Power Dissipation	1 W

Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

NOTES:

1. The ambient temperature, (T_A) is specified here for operation at frequencies up to that frequency determined by the minimum cycle time. Operation at higher cycle rates with reduced ambient temperatures and higher power dissipation is permissible, however, provided AC operating parameters are met.
2. All voltages are referenced to V_{SS} = 0 V.
3. I_{DD} depends on frequency of operation. Maximum current is measured at the fastest cycle rate.
4. I_{CC} depends upon output loading. The V_{CC} supply is connected to the output buffer only. During readout of HIGH level data, V_{CC} is connected through a low impedance (135Ω typ) to Data Out. At other times I_{CC} consists of leakage currents only.
5. Output voltage will swing from V_{SS} to V_{CC} when activated with no current loading. For purposes of maintaining data in standby mode, V_{CC} may be reduced to V_{SS} without affecting refresh operations or data retention. However, the $V_{OH(min)}$ specification is not guaranteed in this mode.
6. Effective capacitance calculated from the equation $C = I\frac{\Delta t}{\Delta V}$ with ΔV = 3 V and power supplies at normal levels.
7. The specifications for $t_{RC(min)}$, $t_{RWC(min)}$ and $t_{PC(min)}$ are used only to indicate cycle time at which proper operation over full temperature range (0°C ≤ T_A ≤ 70°C) is assured.
8. Assumes that $t_{RCD} \leq t_{RCD(max)}$. If t_{RCD} is greater than the maximum recommended value shown in this table, t_{RAC} will increase by the amount that t_{RCL} exceeds the value shown.
9. Assumes that $t_{RCD} \geq t_{RCS(max)}$.
10. Measured with a load equivalent to two TTL loads and 100 pF.
11. $t_{OFF(max)}$ defines the time at which the output achieves the open circuit condition and is not referenced to output voltage levels.
12. Operation within the $t_{RCD(max)}$ limit insures that $t_{RAC(max)}$ can be met. $t_{RCD(max)}$ is specified as a reference point only; if t_{RCD} is greater than the specified $t_{RCD(max)}$ limit, then access time is controlled exclusively by t_{CAC}.
13. $V_{IHC(min)}$ or $V_{IH(min)}$ and $V_{IL(max)}$ are reference levels for measuring timing of input signals. Also, transition times are measured between V_{IHC} or V_{IH} and V_{IL}.
14. t_{WCS} is not a restrictive operating parameter but is included as an electrical characteristic only. If $t_{WCS} \geq t_{WCS(min)}$, the cycle is an early write cycle and the Data Out pin will remain open circuit (high impedance) throughout the entire cycle, otherwise the cycle is a delayed write cycle.
15. The parameters t_{RWL} and t_{CWL} reference WE (for a read-modify-write cycle), to either RAS or CAS respectively, whichever is the first to go HIGH.
16. t_{DS} and t_{DH} are referenced to the leading edge of CAS in early write cycles, and to the leading edge of WE in delayed write or read-modify-write cycles.
17. t_{RWD} and t_{CWD} are not restrictive operating parameters but are included in the data sheet as electrical characteristics only:

    If $t_{CWD} + t_T \leq t_{CWD(min)}$, the Data Out latch will remain in the high impedance state.

    If $t_{CWD} \geq t_{CWD(max)} + t_T$, the Data Out latch will contain the data read from the selected cell.

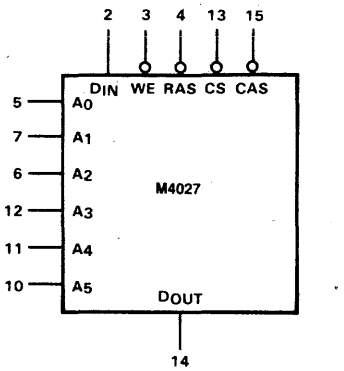
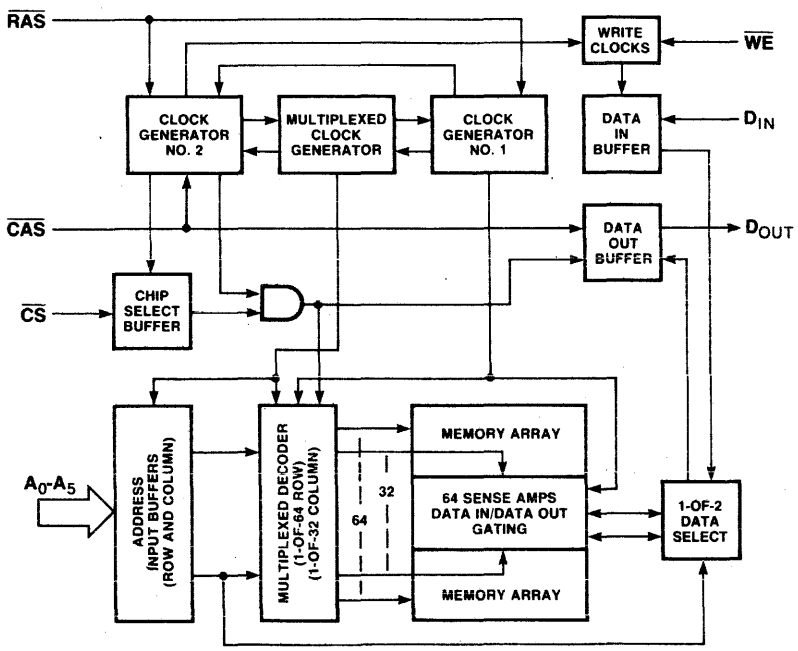
M4027



4096 x 1 DYNAMIC RANDOM ACCESS MEMORY

FAIRCHILD ISOPLANAR SILICON GATE MOS

GENERAL DESCRIPTION – The M4027 is a 4096-bit MOS Dynamic Random Access Memory configured as 4096 one-bit words, and which is manufactured using Fairchild's n-channel silicon gate, Isoplanar process. The use of the single-transistor memory cell along with address multiplexing techniques permits the packaging of the M4027 in a standard 16-pin dual in-line package. The use of this package allows construction of highly dense memory systems utilizing widely available automated testing and insertion equipment.



- **INDUSTRY STANDARD 16-PIN DUAL IN-LINE PACKAGE**
- **LOW CAPACITANCE, TTL-COMPATIBLE INPUTS (INCLUDING CLOCKS)**
- **3-STATE TTL-COMPATIBLE OUTPUT**
- **ON-CHIP LATCHES FOR ADDRESSES, CHIP SELECT, DATA INPUT, DATA OUTPUT**
- **ENHANCED PERFORMANCE WITH GATED CAS, RAS-ONLY REFRESH AND PAGE-MODE CAPABILITY**
- **ACCESS TIME: 150 ns TO 300 ns**
- **PAGE MODE ACCESS: AS FAST AS 100 ns**
- **LOW POWER:**
  - **ACTIVE POWER: 470 mW MAXIMUM**
  - **STANDBY POWER: 27 mW MAXIMUM**
  - **STANDBY POWER (INCLUDING REFRESH): 36 mW MAXIMUM**
- **INPUTS PROTECTED AGAINST STATIC CHARGE**
- **STANDARD ±10% SUPPLIES (+12 V, +5 V, and −5 V)**

FUNCTIONAL DESCRIPTION

ADDRESSING – The 12 address bits required to decode one-of-4096 cell locations are multiplexed to the six address pins and latched into the on-chip row and column address latches. Row Address Strobe ($\overline{RAS}$) latches the six row address bits onto the chip. Column Address Strobe ($\overline{CAS}$) latches the six column address bits plus Chip Select ($\overline{CS}$) onto the chip. As $\overline{CS}$ is not required until well into the cycle, its decoding time does not add to the system access or cycle time. Since the internal circuitry allows the column information to be externally applied to the chip before it is actually required, the hold time requirements for column address and $\overline{CS}$ are also referenced to $\overline{RAS}$. This gated $\overline{CAS}$ feature allows the system designer to compensate for timing skews that may be encountered in the multiplexing operation. Additional timing margin is gained because column address is not required until $\overline{CAS}$ makes its negative transition. The timing is further simplified by the positive transition of $\overline{CAS}$ not being referenced to the positive transition of $\overline{RAS}$. In fact, $\overline{CAS}$ need not go HIGH until the beginning of the next cycle.

DATA INPUT/OUTPUT – Data to be written into the selected cell is latched into an on-chip register by the combination of $\overline{CAS}$ and Write Enable ($\overline{WE}$) while $\overline{RAS}$ is active. The later of these two signals ($\overline{CAS}$ or $\overline{WE}$), making its negative transition, is the strobe for the Data In register. This permits several options in the write timing. In a write cycle, if $\overline{WE}$ is activated prior to $\overline{CAS}$, Data In (D_{IN}) is strobed by $\overline{CAS}$ and the set-up and hold times are referenced to this signal. If the D_{IN} is not available at $\overline{CAS}$ time or the cycle is a read-write or read-modify-write cycle, then $\overline{WE}$ must be delayed until after $\overline{CAS}$ goes active. In this delayed write mode, the D_{IN} set-up and hold times are referenced to $\overline{WE}$.

At the beginning of a memory cycle, the state of the Data Out latch and buffer depend on the previous memory cycle. Changes in the condition of the Data Out latch are initiated by $\overline{CAS}$. The negative transition of $\overline{CAS}$ causes the Data Output (D_{OUT}) to unconditionally go to its open-circuit state. It will remain open-circuited until after the access time has elapsed. At access time, the D_{OUT} will assume the proper state for the type of cycle performed. If the cycle is a read, read-modify-write, or a delayed write cycle and the chip is selected, then the D_{OUT} latch and buffer will contain the data from the selected cell. This output data is the same polarity (not inverted) as the input data. If the cycle is an early write cycle ($\overline{WE}$ active LOW before $\overline{CAS}$ goes LOW) and the chip is selected, then D_{OUT} will contain the input data. Once D_{OUT} goes active, it will remain valid until the next negative transition of $\overline{CAS}$. If the cycle is a $\overline{CAS}$-only cycle (no $\overline{RAS}$ signal), then D_{OUT} will assume the open-circuit state. The same is true for normal cycles (both $\overline{RAS}$ and $\overline{CAS}$ present) when the chip is unselected. D_{OUT} remains in the open-circuit state until the next negative transition of $\overline{CAS}$. $\overline{RAS}$-only refresh cycles (no $\overline{CAS}$) have no effect on the D_{OUT}. However, when $\overline{RAS}$-only-refresh cycles are continued for extended periods of time, D_{OUT} may eventually go open-circuit. If the chip is unselected, it will not accept a write command and the D_{OUT} will remain in the open-circuit state.

INPUT/OUTPUT LEVELS – All inputs, including the two address strobes, interface directly with TTL. The high-impedance, low-capacitance input characteristics simplify input driver selection by allowing use of standard logic elements rather than specially designed driver elements. Termination resistors are normally required in a system to prevent ringing and control transition times of input signals due to line inductance and reflections. In high-speed memory systems, transmission line techniques must be employed on the signal lines to achieve optimum system speeds. Series termination may be employed at some degradation of system speed.

The 3-state output buffer is a low impedance to V_{CC} for a logic "1" and a low impedance to V_{SS} for a logic "0". The output resistance to V_{CC} is 420 Ω maximum and 135 Ω typically. The output resistance to V_{SS} is 125 Ω maximum and 35 Ω typically. The separate V_{CC} pin allows the output buffer to be powered from the supply voltage of the logic to which the chip is interfaced. During battery standby operation, the V_{CC} pin may be unpowered without affecting the M4027 refresh operation. This allows all system logic, except the $\overline{RAS}$ timing circuitry and the refresh address logic, to be turned off during battery standby to conserve power.

REFRESH – Refresh of the cell matrix is accomplished by performing a memory cycle at each of the 64 row addresses every 2 ms or less. Any cycle, in which $\overline{RAS}$ occurs, accomplishes a refresh operation. Any read cycle refreshes the selected row, regardless of the state of $\overline{CS}$. A write, read-write or read-modify-write cycle also refreshes the selected row, but the chip should be unselected to prevent writing data into the selected cell. Refresh may be accomplished with $\overline{RAS}$-only refresh cycles in which $\overline{RAS}$ is the only active signal. In this case the state of the output is not affected. However, after extended periods of standby using $\overline{RAS}$-only refresh the output may eventually become open-circuit. The output buffer will regain activity with the first cycle in which $\overline{CAS}$ is active.

©IC MASTER 1978

PAGE MODE OPERATION – The "Page Mode" feature of the M4027 allows successive memory operations at multiple column locations of the same row address with increased speed without an increase in power. This is accomplished by strobing the row address into the chip and keeping $\overline{RAS}$ active throughout all successive memory cycles with common row addresses. This page mode operation will not dissipate the power associated with the negative transition of $\overline{RAS}$. The time required to strobe in a new row address is also eliminated, thereby decreasing the access and cycle times. $\overline{CS}$ is operative in page mode cycles just as in normal cycles. It is not necessary that the chip be selected during the first operation of a series of page cycles. Likewise, $\overline{CS}$ can be used to select or deselect any cycle(s) in a series of page cycles. This feature allows the page boundary to be extended beyond the 64-column locations in a single chip. The page boundary can be extended by applying $\overline{RAS}$ to multiple 4K memory blocks and decoding $\overline{CS}$ to select the proper block.

POWER DISSIPATION/STANDBY MODE – Most of the circuitry used in the M4027 is dynamic and draws power only as the result of an address strobe edge. Because power is not drawn during the time the strobe is active, the dynamic power is a function of operating frequency. Typically, the power is 170 mW at 1 μs cycle time with a worst-case power of less than 470 mW at 320 ns cycle time. To reduce the overall system power, $\overline{RAS}$ should be decoded and supplied to only the selected chips. The $\overline{CAS}$ should be supplied to all the chips (to turn off the unselected outputs). Those chips that do not receive $\overline{RAS}$ will not dissipate any power on $\overline{CAS}$ edges, except for that required to turn off the outputs. If $\overline{RAS}$ is decoded and supplied to the selected chips, then the $\overline{CS}$ input of all chips can be at a logic 0. For refresh cycles, however, either $\overline{CS}$ or $\overline{CAS}$ must be held to prevent several wire-OR outputs from turning on with opposing force. Note that the M4027 will dissipate considerably less power when the refresh operation is accomplished with a "$\overline{RAS}$-only" cycle as opposed to a normal $\overline{RAS}/\overline{CAS}$ memory cycle.

POWER UP – The M4027 requires no particular power supply sequencing so long as the Absolute Maximum Rating Conditions are observed. However, in order to insure compliance with the Absolute Maximum Ratings, it is recommended that power supplies be sequenced at power up such that V_{BB} is applied first and removed last. V_{BB} should never be more positive than V_{SS} when power is applied to V_{DD}.

Under system failure conditions in which one or more supplies exceed the specified limits, significant additional margin against catastrophic device failure may be achieved by forcing $\overline{RAS}$ and Data Out to the inactive state.

After power is applied to the device, the M4027 requires several cycles before proper device operation is achieved. The same is true after an interval of time (≥2 ms) has elapsed during which the memory was powered, but not refreshed. Any 8 cycles which perform refresh are adequate for this purpose.

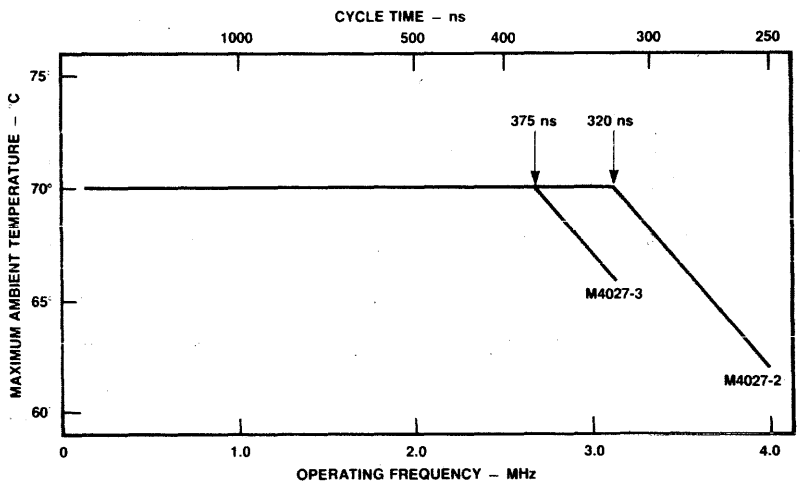

FIG. 1. Maximum Ambient Temperature Versus Cycle Time For Extended Frequency Operation

©IC MASTER 1978

ABSOLUTE MAXIMUM RATINGS

Voltage of any pin relative to V_{BB}	−0.5 V to +20.0 V
Voltage of V_{DD} and V_{CC} relative to V_{SS}	−1.0 V to +15 V
Voltage on V_{BB} relative to V_{SS} when $V_{DD} > V_{SS}$	0 V
Operating Temperature (Ambient)	0°C to 70°C
Storage Temperature (Ambient)	−65°C to +150°C
Short Circuit Output Current	50 mA
Power Dissipation	1W

Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may effect device reliability.

DC REQUIREMENTS: T_A = 0°C to 70°C (See Notes 1 and 2)

NOTES:

1. The ambient temperature, (T_A) is specified here for operation at frequencies up to that frequency determined by the minimum cycle time. Operation at higher cycle rates with reduced ambient temperatures and higher power dissipation is permissible, however, provided AC operating parameters are met. See derating curve in Figure 1.
2. All voltages are referenced to V_{SS} = 0 V.
3. I_{DD} depends on frequency of operation. Maximum current is measured at the fastest cycle rate. I_{DD} current for page mode operation depends on the number of page cycles because of the $\overline{RAS}$ pulse edges. The level specified assumes 30 page cycles with minimum t_{CAS} and t_{CP}.
4. I_{CC} depends upon output loading. The V_{CC} supply is connected to the output buffer only. During readout of HIGH level data, V_{CC} is connected through a low impedance (100 Ω typ) to Data Out. At other times I_{CC} consists of leakage currents only.
5. Output voltage will swing from V_{SS} to V_{CC} when activated with no current loading. For purposes of reducing power in the standby mode, V_{CC} may be reduced to V_{SS} without affecting refresh operations or data retention. However, the $V_{OH(min)}$ specification is not guaranteed in this mode. V_{OH} is measured with I_{OUT} = −5.0 mA and V_{OL} is measured with I_{OUT} = 3.2 mA.
6. All device pins at 0 V except V_{BB} which is at −5 V and the pin under test which is at +10 V.
7. Output is disabled (open-circuit) and $\overline{RAS}$ and $\overline{CAS}$ are both at a logic "1". 0 V ≤ V_{OUT} ≤ +10 V.
8. Capacitance measured with Boonton Meter of effective capacitance calculated from the equation: C = IΔt/Δ V with current equal to a constant 20 mA, and Δ V = 3 V.
9. V_{IHC}(min) or V_{IH}(min) and V_{IL}(max) are reference levels for measuring timing of input signals. Also, transition times are measured between V_{IHC} or V_{IH} and V_{IL}. AC measurements assume t_T = 5 ns.
10. The specifications for $t_{RC(min)}$, $t_{RWC(min)}$ and $t_{PC(min)}$ are used only to indicate cycle time at which proper operation over full temperature range (0°C ≤ T_A ≤ 70°C) is assured. See Note 1 and the derating curve in Fig.1.
11. Assumes that $t_{RCD} \leq t_{RCD(max)}$. If t_{RCD} is greater than the maximum recommended value shown in this table, t_{RAC} will increase by the amount that t_{RCD} exceeds the value shown.
12. Assumes that $t_{RCD} \geq t_{RCD(max)}$.
13. Measured with a load equivalent to two TTL loads and 100 pF.
14. $t_{OFF(max)}$ defines the time at which the output achieves the open circuit condition and is not referenced to output voltage levels.
15. Operation within the $t_{RCD(max)}$ limit insures that $t_{RAC(max)}$ can be met. $t_{RCD(max)}$ is specified as a reference point only; if t_{RCD} is greater than the specified $t_{RCD(max)}$ limit, then access time is controlled exclusively by t_{CAC}.
16. t_{WCS} is not a restrictive operating parameter but is included as an electrical characteristic only. If $t_{WCS} \geq t_{WCS(min)}$, the cycle is an early write cycle and the Data Out pin will contain the data written into the selected cell.
17. The parameters t_{RWL} and t_{CWL} reference $\overline{WE}$ (for a read-modify-write cycle), to either $\overline{RAS}$ or $\overline{CAS}$ repectively, whichever is the first to go HIGH.
18. t_{DS} and t_{DH} are referenced to the leading edge of $\overline{CAS}$ in early write cycles, and to the leading edge of $\overline{WE}$ in delayed write or read-modify-write cycles.
19. t_{RWD} and t_{CWD} are not restrictive operating parameters but are included in the data sheet as electrical characteristics only:
    If $t_{CWD} \geq t_{CWD}$(min) and $t_{RWD} \geq t_{RWD}$(min). the data out latch will contain the data read from the selected cell.
    If t_{CWD} does not meet these constraints, then the data out latch will contain indeterminate data at the access time.

ECL ISOPLANAR MEMORY F10470

4096 × 1-BIT FULLY DECODED RANDOM ACCESS MEMORY

FAIRCHILD VOLTAGE COMPENSATED ECL

GENERAL DESCRIPTION – The F10470 is a 4096-bit Read/Write Random Access Memory organized 4096 words by one bit. It is designed for high speed scratch pad, control and buffer storage applications. The Device includes full address decoding on the chip, has separate Data In and non-invertered Data Out lines, and active LOW Chip Select lines. They are compatible with F10K and uncompensated 10K ECL families and include on-chip voltage compensation for improved noise margin.

The F10470 is packaged in a hermetic ceramic 18-pin dual in-line package and is specified for operation over the temperature range 0°C to 75°C.

- **COMPATIBLE WITH F10K AND UNCOMPENSATED 10K ECL LOGIC**
- **TYPICAL READ ACCESS TIME – 30 ns**
- **TYPICAL CHIP SELECT ACCESS TIME – 10 ns**
- **ORGANIZED 4096 WORDS X 1 BIT**
- **OPEN EMITTER OUTPUT FOR EASE OF MEMORY EXPANSION**
- **POWER DISSIPATION 0.25 mW/BIT**
- **POWER DISSIPATION DECREASES WITH INCREASING TEMPERATURE**
- **REPLACES FOUR 1024 BY ONE RAMs**

FAIRCHILD

FUNCTIONAL DESCRIPTION – The F10470 is a fully decoded 4096-bit Random Access Memoy organized 4096 words by one bit. Word selection is achieved by means of a 12-bit address, A_0 thru A_{11}.

One chip Select input is provided for memory array expansion up to 8192 words without the need for external decoding. For larger memories, the fast Chip Select access time permits the decoding of Chip Select, $\overline{CS}$, from the address withoutincreasing address access time.

The read and write operations are controlled by the state of the active LOW Write Enable, $\overline{WE}$ (pin 15). With $\overline{WE}$ held LOW and the chip selected, the data at D_{IN} is written into the addressed location. To read, $\overline{WE}$ is held HIGH and the chip selected. Data in the specified location is presented at D_{OUT} and is non-inverted.

An unterminated emitter-follower output is provided on the F10470 to allow maximum flexibility in output connection. In many applications such as memory expansion, the outputs of many F10470s can be tied together. In other applications the wired-OR is not used. In either case an external 50 Ω pull down resistor to −2 V or an equivalent network must be used to provide a LOW at the output when it is off.

GUARANTEED OPERATING RANGES

PART NUMBER	SUPPLY VOLTAGE (V_{EE})			AMBIENT TEMPERATURE

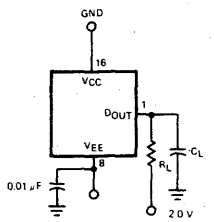
			−200			0°C		



NOTES:
1. Conditions for testing, not shown in the tables are chosen to guarantee operation under "worst case" conditions.
2. The specified Limits represent the "worst case" value for the parameter. Since these "worst case" values normally occur at the temperature extremes, additional noise immunity and guard banding can be achieved by decreasing the allowable system operating ranges.
3. Typical values are at V_{EE} = −5.2 V, T_A = 25°C and maximum loading.
4. Guaranteed with transverse air flow exceeding 400 linear F.P.M. and 2-minute warm-up period. Typical resistance values of the package are:
   θ_{JA} (Junction to Ambient) = 90°C/Watt (still air)
   θ_{JA} (Junction to Ambient) = 50°C/Watt (at 400 F.P.M. air flow)
   θ_{JC} (Junction to Case) = 25°C/Watt
5. The maximum address access time is guaranteed to be the worst case bit in the memory using a pseudorandom testing pattern.
6. DEFINITION OF SYMBOLS AND TERMS USED IN THIS DATA SHEET:
   The symbols and terms used in this data sheet have been chosen to agree with the latest standards of the Electronics Industries Association and the International Electrotechnical Commission. The relative values of the specified conditions and limits will be referenced to an algebraic scale. The extremities of the scale are: "A" the value closest to positive infinity, "B" the value closest to negative infinity.

ECL ISOPLANAR MEMORY
F10415 / F10415A / F100415
1024 x 1-BIT FULLY DECODED RANDOM ACCESS MEMORIES
FAIRCHILD VOLTAGE COMPENSATED ECL

GENERAL DESCRIPTION — These devices are 1024-bit Read/Write Random Access Memories organized 1024 words by one bit. They are designed for high speed scratch pad, control and buffer storage applications. Both include full address decoding on the chip, have separate Data In and non-inverted Data Out lines, and active LOW Chip Select lines.

Fairchild Semiconductor

FUNCTIONAL DESCRIPTION – The F10415, F10415A and F100415 are fully decoded 1024-bit Read/Write Random Access Memories organized 1024 words by one bit. Bit selection is acheived by means of a 10-bit address, A_0 to A_9. One Chip Select input is provided for memory array expansion up to 2048 words without the need for external decoding. For larger memories, the fast chip select access time permits the decoding of Chip Select ($\overline{CS}$) from the address without increasing address access time. The read and write operations are controlled by the state of the active LOW Write Enable ($\overline{WE}$). With $\overline{WE}$ and $\overline{CS}$ held LOW, the data at D_{in} is written into the addressed location. To read, $\overline{WE}$ is held HIGH and $\overline{CS}$ held LOW. Data in the specified location is presented at D_{OUT} and is non-inverted.

An unterminated emitter-follower output is provided to allow maximum flexibility in output connection. In many applications such as memory expansion, the outputs of many F10415s, F10415As or 100415s can be tied together. In other applications the wired-OR is not used. In either case an external 50 Ω pull down resistor to –2 V or an equivalent network must be used to provide a LOW at the output when it is off.

ABSOLUTE MAXIMUM RATINGS (above which the useful life may be impaired)

Storage Temperature	–65°C to +150°C
Temperature (Ambient) Under Bias	–55°C to +125°C
V_{EE} Pin Potential to Ground Pin	–7.0 V to +0.5 V
Input Voltage (dc)	V_{EE} to +0.5 V
Output Current (dc Output HIGH)	–30 mA to +0.1 mA

GUARANTEED OPERATING RANGES

FUNCTIONAL DESCRIPTION – The 93422 is a fully decoded 1024-bit Random Access Memory organized 256 words by four bits. Word selection is achieved by means of an 8-bit address, A_0 thru A_7. Two Chip Select inputs are provided for logic flexibility. For larger memories, the fast chip select access time permits the decoding of Chip Select, CS, from the address without increasing address access time. The read and write operations are controlled by the state of the active LOW Write Enable, WE (pin 20). With WE held LOW and the chip selected, the data at D_{IN} is written into the addressed location. To read, WE is held HIGH and the chip selected. Data in the specified location is presented at D_{OUT}.

NOTES:

1. Conditions for testing, not shown in the Table, are chosen to guarantee operation under "worst case" conditions.
2. The specified LIMITS represents the "worst case" value for the parameters. Since these "worst case" values normally occur at the temperature and supply voltage extremes, additional noise immunity and guard banding can be achieved by decreasing the allowable system operating ranges.
3. Typical values are at V_{CC} = 5.0 V, T_A = +25°C, and MAX loading.
4. The Temperature Ranges are guaranteed with transverse air flow exceeding 400 linear feet per minute. For military range an additional requirement of a two minute warm-up. Temperature range of operation refers to case temperature for Flatpaks and ambient temperature for all other packages. Typical thermal resistance values of the package at maximum temperature are:
   θ_{JA} (Junction to Ambient) (at 400 fpm air flow) = 50°C/Watt, Ceramic DIP; 65°C/Watt, Plastic DIP; NA, Flatpak.
   θ_{JA} (Junction to Ambient) (still air) = 90°C/Watt, Ceramic DIP; 110°C/Watt, Plastic DIP; NA, Flatpak.
   θ_{JC} (Junction to Case) = 25°C/Watt, Ceramic DIP; 25°C/Watt, Plastic DIP; 10°C/Watt, Flatpak.
5. The MAX address access time is guaranteed to be the "worst case" bit in the memory using a pseudo random testing pattern.
6. t_W measured at t_{WSA} = MIN, t_{WSA} measured at t_W = MIN.
7. Duration of short circuit should not exceed one second.

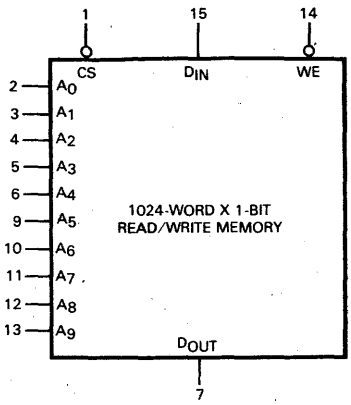
TTL ISOPLANAR MEMORY

1024 x 1-BIT FULLY DECODED RANDOM ACCESS MEMORIES

DESCRIPTION — These devices are 1024-Bit Read/Write Random Access Memories organized 1024 words by one bit and are designed for buffer control storage and high performance main memory applications. The typical access time ranges from 25 ns to 40 ns depending upon the device type. The 93L415 and 93L425 are appropriate for systems requiring low power.



Each 1024-bit memory has full decoding on chip, separate Data Input and Data Output lines and an active LOW Chip Select line. The 93425 and 93L425 have a 3-state output to drive bus organized systems and/or highly capacitive loads and the 93415 and 93L415 have an uncommitted collector output for ease of memory expansion. All of the devices are fully compatible with standard DTL and TTL logic families.

- **FULL MIL AND COMMERCIAL RANGES**
- **3-STATE OUTPUT — 93425 AND 93L425**
- **UNCOMMITTED COLLECTOR OUTPUT — 93415 AND 93L415**
- **NON-INVERTING DATA OUTPUT**
- **ORGANIZED 1024 WORDS x 1 BIT**
- **POWER DISSIPATION 250 mW TYP — 93L415 AND 93L425**
- **POWER DISSIPATION 0.5 mW TYP — 93415 AND 93425**
- **TTL INPUTS AND OUTPUT**
- **POWER DISSIPATION DECREASES WITH INCREASING TEMPERATURE**

93425/93L425 LOGIC DIAGRAM

FUNCTIONAL DESCRIPTION — These devices are fully decoded 1024-Bit Random Access Memories organized 1024 words by one bit. Word selection is achieved by means of a 10-bit address, A_0-A_9. The Chip Select input allows memory array expansion. For large memories, the fast chip select access time permits decoding of the Chip Select ($\overline{CS}$) from the address without affecting system performance. The read and write operations are controlled by the state of the active LOW Write Enable ($\overline{WE}$). With $\overline{WE}$ held LOW and the chip selected, the data at D_{IN} is written into the addressed location. To read, $\overline{WE}$ is held HIGH and the chip selected. Data in the specified location is presented at D_{OUT} and is non-inverted.

93425 and 93L425 Only

The 93425 and 93L425 3-state outputs provide drive capability for higher speeds with high capacitive load systems. The third state (high impedance) allows bus organized systems where multiple outputs are connected to a common bus. During writing, the output is held in the high impedance state.

93415 and 93L415 Only

The 93415 and 93L415 uncommitted collector outputs are provided to allow maximum flexibility in output connection. In many applications such as memory expansion, the outputs of many 93415s or 93L415s can be tied together. In other applications, the wired-OR is not used. In either case, an external pull-up resistor of R_L value must be used to provide a HIGH at the output when it is off. Any R_L value within the range specified below may be used. The minimum R_L value is limited by output current sinking ability. The maximum R_L value is determined by the output and input leakage current which must be supplied to hold the output at V_{OH}. One Unit Load = 40 μA HIGH/1.6 mA LOW.

$$\frac{V_{CC}\,(min)}{I_{OL} - FO\,(1.6)} \leq R_L \leq \frac{V_{CC}\,(min) - V_{OH}}{n\,(I_{CEX}) + FO\,(0.04)}$$

R_L is in kΩ
n = number of wired-OR outputs tied together
FO = number of TTL Unit Loads (UL) driven
I_{CEX} = Memory Output Leakage Current
V_{OH} = Required Output HIGH Level at Output Node
I_{OL} = Output LOW Current

NOTES:
1. Conditions for testing, not shown in the Table, are chosen to guarantee operation under "worst case" conditions.
2. The specified LIMITS represents the "worst case" value for the parameters. Since these "worst case" values normally occur at the temperature and supply voltage extremes, additional noise immunity and guard banding can be achieved by decreasing the allowable system operating ranges.
3. Typical limits are at V_{CC} = 5.0 V, T_A = +25°C, and MAX loading.
4. The Temperature Ranges are guaranteed with transverse air flow exceeding 400 linear feet per minute. For military range an additional requirement of a two minute warm-up. Typical thermal resistance values of the package at maximum temperature are:
   θ_{JA} (Junction to Ambient) (at 400 lpm air flow) = 50°C/Watt, Ceramic DIP; 65°CC/Watt, Plastic DIP; NA, Flatpak.
   θ_{JA} (Junction to Ambient) (still air) = 90°C/Watt, Ceramic DIP; 110°C/Watt, Plastic DIP; NA, Flatpak.
   θ_{JC} (Junction to Case) = 25°C/Watt, Ceramic DIP; 25°C/Watt, Plastic DIP; 10°C/Watt, Flatpak.
5. The MAX address access time is guaranteed to be the "worst case" bit in the memory using a pseudo random testing pattern.
6. t_W measured at t_{WSA} = MIN, t_{WSA} measured at t_W = MIN.
7. Duration of short circuit should not exceed one second.

FUNCTIONAL DESCRIPTION – The 93470 and 93471 are fully decoded 4096-bit Random Access Memories organized 4096 words by one bit. Word selection is achieved by means of a 12-bit address, A_0 thru A_{11}.

The Chip Select input is provided for logic flexibility. For larger memories, the fast Chip Select access time permits the decoding of Chip Select, $\overline{CS}$, from the address without increasing address access time.

The read and write operations are controlled by the state of the active LOW Write Enable, $\overline{WE}$ (pin 5). With $\overline{WE}$ held LOW and the chip selected, the data at D_{IN} is written into the addressed location. To read, $\overline{WE}$ is held HIGH and the chip selected. Data in the specified location is presented at the Data Outputs.

The 93471 has 3-state outputs which provide drive capability for higher speeds with high capacitive load systems. The third state (high impedance) allows bus organized systems where multiple outputs are connected to a common bus.

The 93470 has uncommitted collector outputs to allow maximum flexibility in output connection. In many applications, such as memory expansion, the outputs of several 93470s can be tied together. In other applications the wired-OR is not used. In either case an external pull-up resistor of value R_L must be used to provide a HIGH at the output when it is off. Any value of R_L within the range specified below may be used.

$$\frac{V_{CC(max)}}{8 - \text{F.O. } (1.6)} \leqslant R_L \leqslant \frac{V_{CC(min)} - V_{OH}}{N\,(I_{CEX}) + \text{F.O. } (0.04)}$$

R_L is in kΩ
N = number of wired-OR outputs tied together
F.O. = number of TTL Unit Loads (U.L.) driven
I_{CEX} = Memory Output Leakage Current in mA
V_{OH} = Required Output HIGH level at Output Node

The minimum value of R_L is limited by output current sinking ability. The maximum value of R_L is determined by the output and input leakage current which must be supplied to hold the output at V_{OH}.

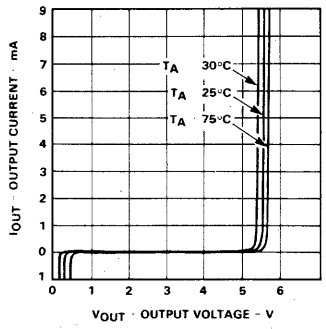
NOTES:
1. Conditions for testing, not shown in the Table, are chosen to guarantee operation under "worst case" conditions.
2. The specified LIMITS represents the "worst case" value for the parameters. Since these "worst case" values normally occur at the temperature and supply voltage extremes, additional noise immunity and guard banding can be achieved by decreasing the allowable system operating ranges.
3. Typical values are at V_{CC} = 5.0 V, T_A = +25°C, and MAX loading.
4. The Temperature Ranges are guaranteed with transverse air flow exceeding 400 linear feet per minute and a two minute warm-up. Temperature range of operation refers to case temperature for Flatpaks and ambient temperature for all other packages. Typical thermal resistance values of the package at maximum temperature are:

   θ_{JA} (Junction to Ambient) (at 400 fpm air flow) = 50°C/Watt, Ceramic DIP; 65°C/Watt, Plastic DIP; NA, Flatpak.
   θ_{JA} (Junction to Ambient) (still air) = 90°C/Watt, Ceramic DIP; 110°C/Watt, Plastic DIP; NA, Flatpak.
   θ_{JC} (Junction to Case) = 25°C/Watt, Ceramic DIP; 25°C/Watt, Plastic DIP; 15°C/Watt, Flatpak.



5. The MAX address access time is guaranteed to be the "worst case" bit in the memory using a pseudo random testing pattern.
6. t_W measured at t_{WSA} = MIN, t_{WSA} measured at t_W = MIN.
7. Duration of short circuit should not exceed one second.

FIELD PROGRAMMABLE READ ONLY MEMORIES

GENERAL DESCRIPTION—Fairchild's family of field programmable ROMs includes 1024, 2048, 4096-bit devices. Each of the five device pairs are identical except for the output stages—the first of each pair has uncommitted collector outputs, the second has 3-state outputs. They are supplied with all bits stored as logic "1" and can be programmed by following the field programming procedure.

ABSOLUTE MAXIMUM RATINGS

Storage Temperature	-65°C to +150°C
Temperature (Ambient) Under Bias	-55C to +125°C
V_{CC}	-0.5V to +7.0V
Input Voltages	-0.5V to +5.5V
Current Into Output Terminal	100mA
Output Voltages— 94317, 93427, 93452, 93453	-0.5V to +5.5V
Output Voltages— 93436, 93446, 93438, 93448	-0.5V to +4.0VV

- **SILICON NITRIDE PROTECTED**
- **FULL MIL AND COMMERCIAL RANGES**
- **FIELD PROGRAMMABLE**
- **FULLY DECODED — ON-CHIP ADDRESS DECODER AND BUFFER**
- **WIRED-OR CAPABILITY**
- **NICHROME FUSE LINKS FOR HIGH RELIABILITY**
- **UNCOMMITTED COLLECTORS — 94317, 93436, 93438, 93450, 93452**
- **3-STATE OUTPUTS — 93427, 93446, 93448, 93451, 93453**

93417/27

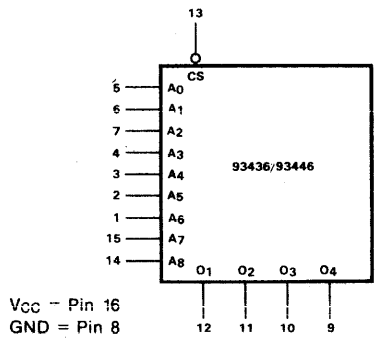
256 × 4-BIT PROGRAMMABLE READ ONLY MEMORY

LOGIC SYMBOL

LOGIC DIAGRAM

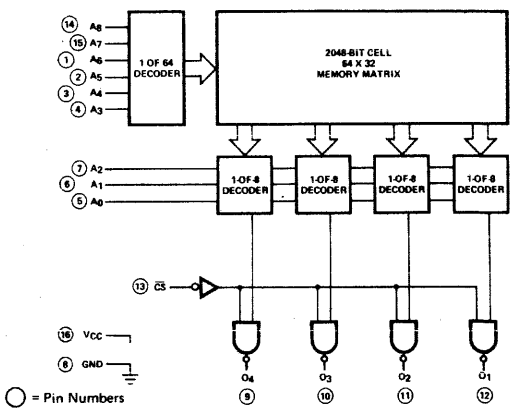
FUNCTIONAL DESCRIPTION - The 93417 and 93427 are bipolar field Programmable Read Only Memories (PROMs) organized 256 words by four bits per word. Open collector outputs are provided for use in wired-OR systems. The 93427 has 3-state outputs which provide active pull-ups when enabled and high output impedance when disabled. Chip Selects are active LOW; conversely, a HIGH (logic "1") on the $\overline{CS_1}$ or $\overline{CS_2}$ will disable all outputs.

The read function is identical to that of a conventional bipolar ROM. That is, a binary address is applied to the A_0 through A_7 inputs, the chip is selected, and data is valid at the outputs after t_{AA} nanoseconds.



PIN NAMES

A_0 — A_7	Address Inputs
$\overline{CS_1}$, $\overline{CS2}$	Chip Select Inputs (Active LOW)
O_1 — O_4	Data Outputs



93436/46

512 × 4-BIT PROGRAMMABLE READ ONLY MEMORY

LOGIC SYMBOL

LOGIC DIAGRAM

FUNCTIONAL DESCRIPTION—The 93436 and 93446 are bipolar field Programmable Read Only Memories (PROMs) organized 512 words by four bits per word. Open collector outputs are provided on the 93436 for use in wired-OR systems. Chip select is active LOW; i.e., a HIGH (logic "1") on the $\overline{CS}$ pin will disable all outputs. The 93446 has 3-state outputs which provide active pull-ups when enabled and high output impedance when disabled.

The read function is identical to that of a conventional bipolar ROM. That is, a binary address is applied to the A_0 through A_8 inputs, the chip is selected, and data is valid at the outputs after t_{AA} nanoseconds.

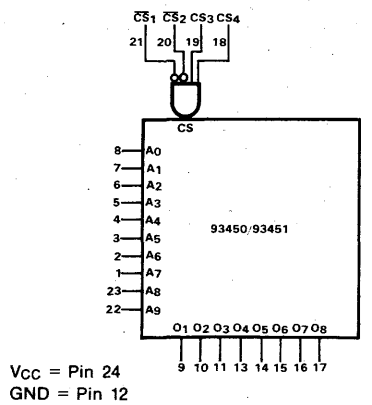
512 × 8-BIT PROGRAMMABLE READ ONLY MEMORY

LOGIC SYMBOL

V_{CC} = Pin 24
GND = Pin 12

LOGIC DIAGRAM

FUNCTIONAL DESCRIPTION—The 93438 and 93448 are bipolar field Programmable Read Only Memories (PROMs) organized 512 words by eight bits per word. Open collector outputs are provided on the 93438 for use in wired-OR systems. The 93448 has 3-state outputs which provide active pull-ups when enabled and high output impedance when disabled. Chip Select follows the logic equation: $\overline{CS_1} \bullet \overline{CS_2} \bullet CS_3 \bullet CS_4 = CS$; i.e., if $\overline{CS_1}$ and $\overline{CS_2}$ are both active LOW and CS_3 and CS_4 are both active HIGH, all eight outputs are enabled; for any other condition all eight outputs are disabled.



The read function is identical to that of a conventional bipolar ROM. That is, a binary address is applied to the A_0 through A_8 inputs, the chip is selected, and data is valid at the outputs after t_{AA} nanoseconds.

PIN NAMES

A_0 — A_8	Address Inputs

1400 Bit Electrically Alterable Read Only Memory

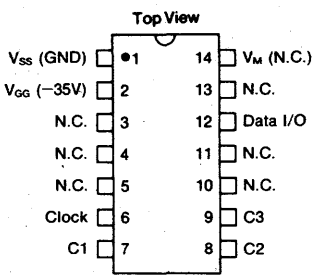
FEATURES

- 100 Word x 14 bit organization
- Word alterable
- 10 years unpowered data storage
- **Write/Erase time 20ms/word**
- Single -35 volt supply
- No voltage switching required
- MOS compatible signal levels

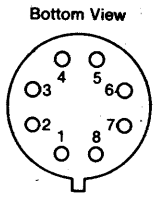
DESCRIPTION

The ER1400 is a serial input/output 1400 bit electrically erasable and reprogrammable ROM, organized as 100 words of 14 bits each. Data and address are communicated in serial form via a one-pin bidirectional bus.

Addressing is by two consecutive one-of-ten codes.



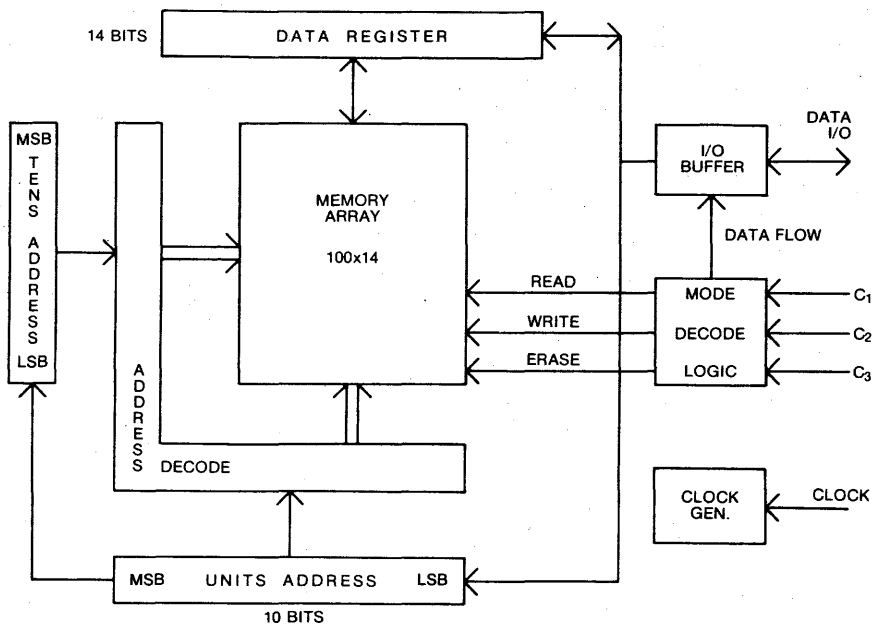
Mode selection is by a 3 bit code applied to C1, C2 and C3.



Data is stored by internal negative writing pulses that selectively tunnel charge into the oxide-nitride interface of the gate insulator of the 1400 MNOS memory transistors. When the writing voltage is removed the charge trapped at the interface is manifested as a negative shift in the threshold voltage of the selected memory transistors.

PIN CONFIGURATIONS

Standard package
14 LEAD DUAL IN LINE



Special Order Package
8 LEAD TO-8 (ER1400T)

1. Data I/O
2. V_M (N.C.)

PIN FUNCTIONS

Name	Function
Data	In the Accept Address and Accept Data modes, this pin is an input pin for address and data respectively. In the Shift Data Out mode this pin is an output pin designed to drive MOS. In Standby, Read, Erase and Write, this pin is left floating.
V_M	Used for testing purposes only. Must be left unconnected for normal operation.
V_{SS}	Chip substrate. Normally connected to ground.
V_{GG}	DC supply. Normally connected to −35 volt supply.
Clock	14kHz timing reference. Required for all operations. May be left at logic zero when device is in standby.
C1,C2,C3	Mode control pins. Their operation is as follows:

C1	C2	C3	Function
0	0	0	Standby - contents of Address and Data Register remains unchanged. Output buffer is left floating.
0	1	1	Accept Address - Data presented at the I/O pin is shifted into the Address Register with each clock pulse. Addressing is by two consecutive one-of-ten codes.
1	0	0	Read - The address word is read from memory into the data register.
1	0	1	Shift Data Out - The output driver is enabled and the contents of the Data Register are shifted out one bit with each clock pulse.
0	1	0	Erase - The word stored at the addressed location is erased to all zeros.
1	1	1	Accept Data - The data register accepts serial data presented at the I/O pin. The Address Register remains unchanged.
1	1	0	Write - The word contained in the Data Register is written into the location designated by the Address Register.
0	0	1	Not Used

512 Bit Electrically Alterable Read Only Memories

FEATURES

- 32x16 Organization
- 5-Bit Addressing
- TTL Compatible
- Chip Select
- Word Alterable
- 10 Year Unpowered Data Storage
- 10 μs Access Time (ER2050)
- 3 μs Access Time (ER2051)
- Write/Erase Time 100ms/word (ER2050), 50ms/word (ER2051)
- +5, -28V Supplies
- No Voltage Switching Required

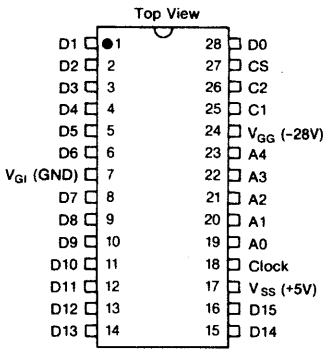
NOTE: Use ER2051 for all new designs.

DESCRIPTION

The ER2050 and ER2051 are fully decoded 32 × 16 electrically erasable and reprogrammable ROMs. Write, erase, and read voltages are switched internally via a 2-bit code applied to C1 and C2.

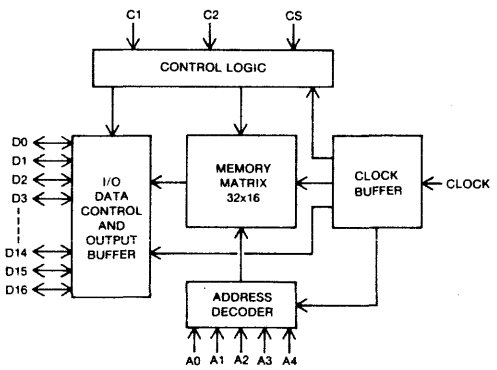
Data is stored by applying negative writing pulses that selectively tunnel charge into the oxide-nitride interface at the gate insulator of the 512 MNOS memory transistors. When the writing voltage is removed the charge trapped at the interface is manifested as a negative shift in the threshold voltage of the selected memory transistors.

Two TTL compatible control pins switch voltages internally for write, read and erase control.



OPERATION

Data is stored in a two transistor memory cell. After the cell is preconditioned by an erase signal (which lowers the threshold of both transistors), data is written into one of the transistors lowering its threshold. A sensing flip flop is used to read the memory cell and presents a logic high or low to the output depending on which transistor is "written".



It is important to note two things: first, that an erase is required before a write to precondition the cell, and second, that after an erase, both transistors will have the same threshold voltage and valid data will not be present at the output.

PIN CONFIGURATION

28 LEAD DUAL IN LINE

BLOCK DIAGRAM

PIN FUNCTIONS

A_0-A_4	5-Bit Word Address
D_0-D_{15}	Data input and output pins
CS	Chip Select. Chip selected at logic "1". When chip select is at logic "0", outputs are open circuit, read, write and erase are disabled. Power is reduced.
C1, C2	Mode Control Inputs C1 C2 1 1 Hold Mode: output data from previous read operation stored at output pins. (For the ER2050 only. This code is "read mode" for the ER2051). 0 1 Erase Mode: stored data is erased at addressed location. 1 0 Read Mode: addressed data read after clock pulse. Output data retained at output pins until next read operation. 0 0 Write Mode: input data written at addressed location. Clock not required. NOTE: Care must be exercised to ensure that CS is held at logic "0" during power up or power down to protect all addresses from spurious write or erase inputs.
CLK	Clock Input. Pulse to logic "1" for read operation. The clock may be repetitive or may simply be pulsed when data is to be read. When the clock is repetitive the ER2050 should be maintained in the standby mode when data is not being read, as every clock pulse will constitute a read operation. When the clock is not repetitive data will remain valid for 20 to 60 seconds; the outputs will then become open circuit until another clock pulse is received. The clock should not be repetitive for the ER2051.
V_{SS}	Substrate supply. Normally at +5 volts.
V_{GI}	Ground Input.
V_{GG}	Power Supply Input. Normally at -28 volts.

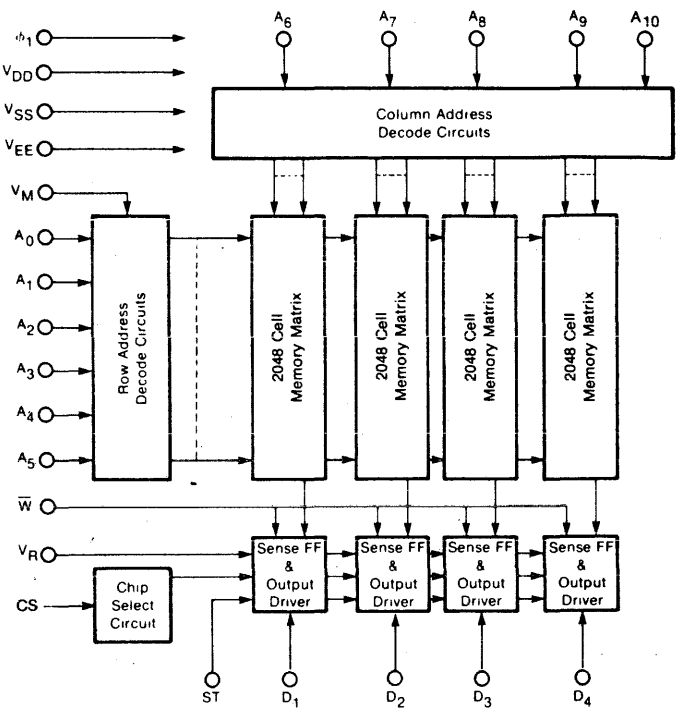
8192 Bit Electrically Alterable Read Only Memories

FEATURES

- 2048 x 4 Organization
- 11-Bit Binary Addressing
- Chip Select Input
- Electrically Reprogrammable
- 2.6 μs Access Time (ER2800)
- 1.65 μs Access Time (ER2805)
- 20 ms/4-bit Word Write Time
- 100 ms Simultaneous Erasure of All Data
- Minimum Data Retention—2 x 10^{11} Read Accesses/Word Between Refresh
- Three-State Outputs
- Unpowered, Nonvolatile Data Storage—10 Years at +70°C
- Control, Address and Data Inputs TTL Compatible.

PIN CONFIGURATION

24 LEAD DUAL IN LINE



DESCRIPTION

The ER2800 and ER2805 are fully decoded 2048 × 4-bit electrically erasable and reprogrammable ROMs utilizing second-generation MNOS epitaxial processing technology.

Data is stored by applying negative writing pulses that selectively tunnel charge into the oxide-nitride interface at the gate insulator of the 8192 MNOS memory transistors. When the writing voltage is removed, the charge trapped at the interface is manifested as a negative shift in the threshold voltage of the selected memory transistors.

Stored data may be accessed a minimum of 2 × 10^{11} times without refresh and is non-volatile in the unpowered state in excess of ten years. Data is erased by applying a V_{SS}-28V pulse to the erase substrate of the device. Data can be erased and rewritten up to a maximum of 10^6 times. All outputs are at logic high when the device is in the erased state.

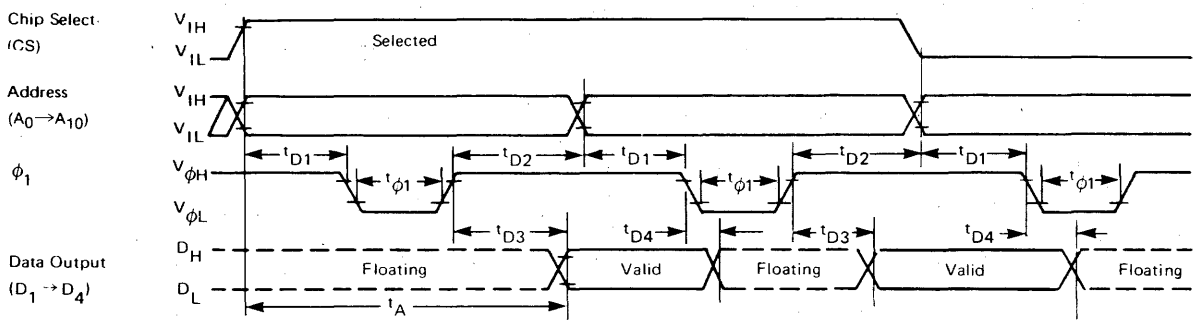
ERASE CYCLE CHARACTERISTICS, T_A = 0°C to +70°C

Symbol	Parameter	Min	Typ	Max	Units
t_E	V_{EE} erase pulse width	100	—	1000	ms
t_r, t_f	V_{EE} rise time, V_{EE} fall time	0.01	—	1.0	ms
t_o	Write-erase overlap	10	—	—	μs

WRITE CYCLE CHARACTERISTICS, T_A=0°C to +70°C ($ST=V_{DD}$) (SEE NOTE 3)

Symbol	Parameter	Min	Typ	Max	Units
$N\phi_W$	Number of ϕ_1 write pulses at 100 μs ±10%, 5 μs min. dead time between pulses)	100	200	300	Pulses
t_{D7}	Write control rise to pulsed ϕ_1 rise delay	500	—	—	ns
t_{D8}	Address change and chip select fall to pulsed ϕ_1 rise delay	500	—	—	ns
t_{D9}	Pulsed ϕ_1 fall to address and chip select change delay	0.0	—	—	μs
t_{D10}	Data input change to pulsed ϕ_1 rise delay	0.0	—	—	μs
t_{D11}	Pulsed ϕ_1 fall to data input change delay	0.0	—	—	μs
N_W	Number of times word may be rewritten	—	—	10^6	—



NOTES:
1. Due to the dynamic nature of the circuit a "ϕ_1 NOT" time in excess of 40 μsec. may result in a floated output condition. Consequently data must be resampled with a 40 μsec. time period following the fall of ϕ_1 to ensure its validity.
2. Several seconds may be required following a programming operation for the circuit to become operable in the read mode. If data is to be verified immediately following programming, a forward current of +1 mA ±10% may be forced into the erase substrate junction (Pin 4, V_{EE}), for a period not to exceed 10 milliseconds, to quickly dissipate charge trapped at internal circuit nodes.
3. Maximum power dissipation occurs during programming. When programming multichip systems where the application of programming voltages is required for several minutes, forced air cooling is recommended to reduce package temperature. Power is not reduced when chip is deselected.
4. All typical values are at +25°C and nominal voltages.

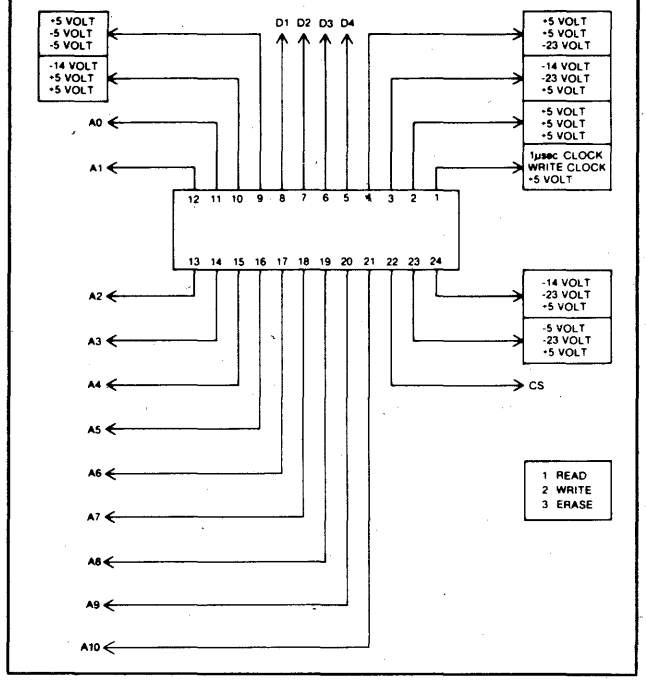
PIN FUNCTIONS

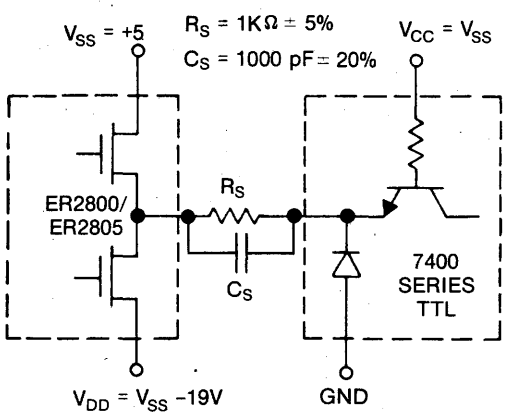
Chip Select (CS)
Must be in the high state to enable the data output terminals or write data into the device.

Data Input/Output (D1—D4)
D1 through D4 are bidirectional data terminals. Data are entered on these terminals during the write cycle and read out during the read cycle. When deselected, these terminals are in a floating condition.



Write Control ($\overline{W}$)
The write control terminal must be in the low state in order to write data into the device.

Strobe (ST)
A strobe input is provided for delayed data clockout. In applications where this feature is not desired, the strobe terminal should be maintained at VDD throughout the entire read cyle. The ST input is high-level and not TTL-compatible.



Phase One (ϕ1)
During the write operation, multiple 100μs pulses must be applied to the ϕ1 terminal to fully shift the memory transistor threshold voltge to its most negative state. This is required for voltage bootstrapping in the row-selection circuitry. The ϕ1 input is high level and not TTL-compatible.

NOTE: All control, address and data inputs are TTL-compatible with pull-up resistors.

BLOCK DIAGRAM

DESCRIPTION

The ER3400 and ER3401 are word alterable ROMs intended for use as read-mostly memories. Each operates with one clock, CHIP ENABLE ($\overline{CE}$), which also serves for chip selection. All other pins of each device can be paralleled with other EAROMs.

Any one of four possible operating modes can be selected by setting the proper binary code on the C0-C1 control lines and pulsing the device with $\overline{CE}$. The four modes are Read, Write, Word Erase and Block Erase. The ER3400/3401 will sense the control lines and change modes only when pulsed by $\overline{CE}$. When in the Read mode, data is read during each $\overline{CE}$ pulse. Writing or erasing of a word continues for as long as the device is in the Write or Erase mode. Each write or erase word cycle must be ended by a dummy read operation.

A WRITE ENABLE ($\overline{WE}$) input pulse indicates to the ER3400/3401 that the data on the D_0-D_3 data input/output lines is valid input data. This data is then stored internally for use during the write operation.

No particular order of power supply sequencing on or off is required for the ER3400. Circuits are provided to force the device into the read mode during power turn on. Erasing and writing are inhibited if V_{DD} or V_{GG} are not at proper operating levels.

For the ER3401, V_{GG} must be turned on after V_{CC} is stable and removed before V_{CC} is turned off.

PIN FUNCTIONS

A_0-A_9	10-Bit Word Address
D_0-D_3	Data input and output pins
$\overline{CE}$	Chip Enable. Chip selected when $\overline{CE}$ is pulsed to logic "0".
C_0, C_1	Mode Control Inputs
	C0 C1
	0 1 Block Erase Mode: erase operation performed on all words.
	1 1 Word Erase Mode: stored data is erased at addressed location.
	0 0 Read Mode: addressed data read after leading edge of $\overline{CE}$ pulse.
	1 0 Write Mode: input data written at addressed location.
$\overline{WE}$	Write Enable. Input data read when $\overline{WE}$ is pulsed to logic "0".
V_{SS}	Substrate supply. Normally at +5 volts.
V_{GI}	Ground Input
V_{DD}	Power Supply Input. Normally at -12 volts.
V_{GG}	Power Supply Input. Normally at -30 volts.

ELECTRICAL CHARACTERISTICS

Maximum Ratings*

All inputs and outputs (with respect to V_{SS}) ..... -40V to +0.3V
Storage temperature (with data retention) ..... -40°C to +70°C
Storage temperature (without data retention) ..... -65°C to +150°C
Soldering temperature of leads (10 seconds) .....+300°C

*Exceeding these ratings could cause permanent damage. Functional operation of this device at these conditions is not implied—operating ranges are specified below.

Standard Conditions (unless otherwise noted)

V_{SS} = +5V ±5%
V_{DD} = -12V ±5%
V_{GG} = -30V ±5%
V_{GI} = GND
Operating Temperature (T_A) = 0°C to =70°C

Characteristic	Symbol	Min	Typ**	Max	Units	Conditions
DC CHARACTERISTICS						
Input Logic "1"	V_{IH}	V_{SS}-1.5	—	V_{SS}+0.3	Volts	
Input Logic "0"	V_{IL}	-10	—	0.8	Volts	
Output Logic "1"	V_{OH}	V_{SS}-1.5	—	—	Volts	I_{OH} = -2mA
Output Logic "0"	V_{OL}	—	—	0.4	Volts	I_{OL} = 2mA
Control Input Leakage	I_{LC}	—	—	-2.0	μA	V_{IN} = V_{SS} -15 Volts

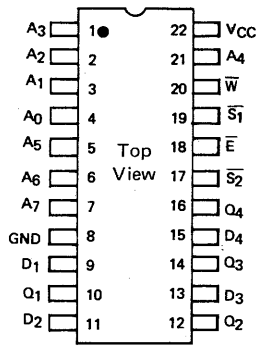
Product Brief



HM-6551

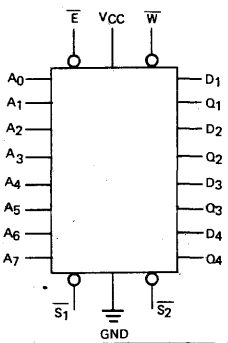
256 x 4 CMOS RAM

Features

- LOW STANDBY POWER . . . . . 55 μW MAX
- LOW OPERATING POWER . . . . . 22mW/MHZ MAX
- FAST ACCESS TIME . . . . . 220nsec MAX
- DATA RETENTION VOLTAGE . . . . . 2.0 volts MIN
- TTL COMPATIBLE IN/OUT
- HIGH OUTPUT DRIVE – 2 TTL LOADS
- INTERNAL LATCHED CHIP SELECT
- HIGH NOISE IMMUNITY
- ON CHIP ADDRESS REGISTERS
- LATCHED OUTPUTS
- THREE STATE OUTPUTS
- MILITARY AND INDUSTRIAL TEMPERATURE RANGES

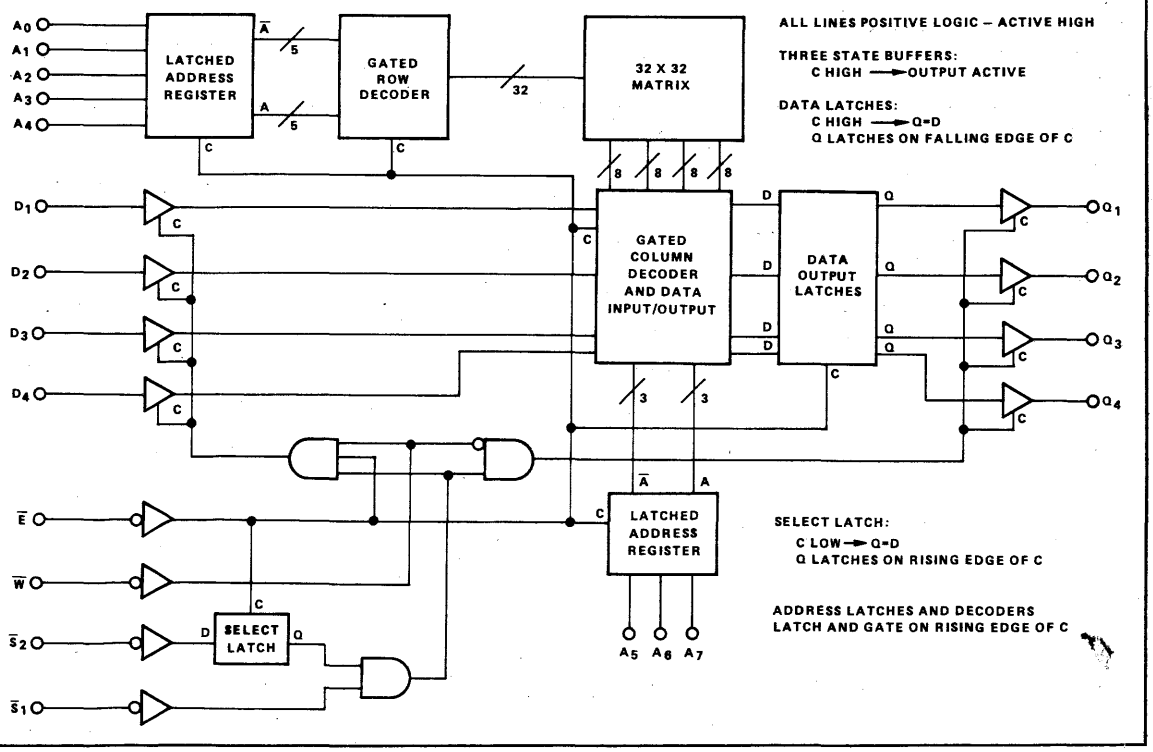
Pinout

A – ADDRESS INPUT
E – CHIP ENABLE
S – CHIP SELECT
W – WRITE ENABLE
D – DATA INPUT
Q – DATA OUTPUT



Description

The HM – 6551 is a 256 by 4 static CMOS RAM fabricated using self-aligned silicon gate technology. Synchronous circuit design techniques are employed to achieve high performance and low power operation.



On chip latches are provided for addresses and data outputs allowing efficient interfacing with microprocessor systems. The data output buffers can be forced to a high impedance state for use in expanded memory arrays.

The HM – 6551 is a fully static RAM and may be maintained in any state for an indefinite period of time. Data retention supply voltage and supply current are guaranteed over temperature.

Logic Symbol

Description

The HM-6611 is part of a family of fusible link CMOS PROM's, featuring three-state outputs. This device is static, TTL compatible, and has a 100 μA max. standby current over temp. at a V_{CC} of 5 volts. 10V and full Mil. temp. devices are available. Chip Select ($\overline{CS}$) is used to place the device in the standby state and also forces the outputs into the high impedance state when it is high. Program Enable ($\overline{PE}$) is used only during programming, and must be connected to V_{CC} in the system. Pinout is similar to bipolar PROM's and 256 x 4 CMOS RAM's for flexibility in P.C. board layout and memory allocation by type.

Test Characteristics

Programming

BACKGROUND INFORMATION

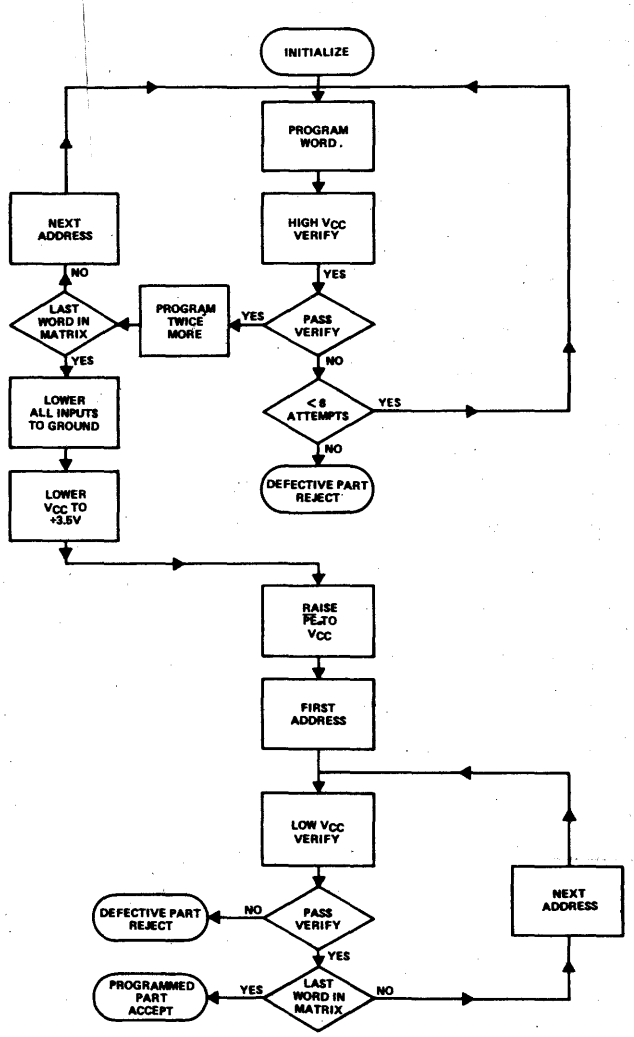
The HM-6611 is a 256 x 4 CMOS Programmable Read-Only Memory. It is programmed by the controlled application of programming pulses to selected memory cells. These pulses permanently alter the logic state of the memory cell. The memory array is manufactured with each cell set to the high or "1" logic state. The user may select any memory cell and permanently change its logic state to a "0" or low by programming.

Programming is accomplished by addressing the word to be programmed, applying the programming pulses, and verifying the data programmed. The verification is performed at high voltage (V_{CC}) during the programming sequence, and at low voltage after all programming is completed.

PROGRAMMING SYSTEM CHARACTERISTICS:

1. Power source for the device to be programmed (V_{CC}) variable from +3.0 to +11.0 volts, current capability of 500mA average and 1 amp dynamic currents.
2. Programming pulse is a negative 27.0 volt (±3.0V) pulse of 4 millisecond duration (±25%), rise and fall times of 4 to 400 microseconds, capable of 400mA average and 1 amp dynamic currents.
3. Data output load devices (switchable) capable of sinking 10mA from the output pin without rising more than 0.6 volts above ground. Open collector, open drain or discrete devices with resistive pull-ups of 4.7K to 47K is the recommended implementation.
4. Data output sensing devices capable of sensing valid logic levels ($V_{OH} \geq 70\%\ V_{CC}$, $V_{OL} \leq 20\%\ V_{CC}$).*
5. Address buffers able to maintain high state voltages of $\geq 70\%$ of V_{CC} at both high and low V_{CC},* and low state voltages $\leq 20\%$ V_{CC} at both high and low V_{CC}.
6. Timing and control logic suitable to sequence the required functions.

*Never allow any input to rise more than 0.3 volts above V_{CC}.



PROGRAMMING PROCEDURE:

OVERALL:

1. Address and program word.
2. Verify data output at high V_{CC} (10V ±10%)
   a. If device fails to verify repeat program – verify sequence (reject device as defective after 8 programming attempts at any one word).
   b. If device passes verify repeat programming sequence twice more then return to step 1 to program the next word.
   c. If device passes verify at the last location to be programmed continue to step 3.
3. Lower V_{CC} to 3.5V ±.5V and verify each location in the matrix.
   a. If any location fails to verify reject the device as defective.
   b. If all locations pass verify the part is properly programmed.

©IC MASTER 1978

PROGRAMMING SEQUENCE FLOW CHART

PROGRAMMING STEPS:

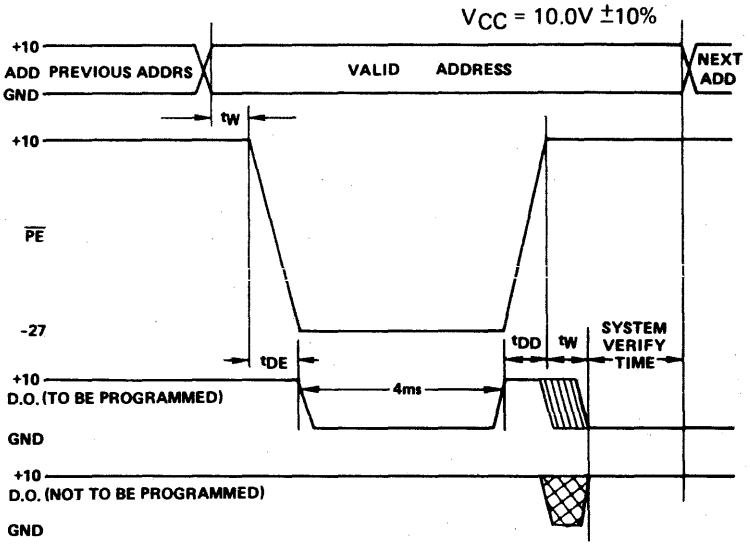
INITIALIZE:

V_{CC} = +10.0V ±10%
$\overline{PE}$ = V_{CC}
$\overline{CE}$ = GND (not used during programming)

1. Setup the address of the word to be programmed.
2. Wait 500 nanoseconds or more.
3. Initiate the negative $\overline{PE}$ pulse described in System Characteristics # 2.
4. After the $\overline{PE}$ pulse has crossed zero (ground) going negative enable the data output load devices of each output pin that is to be programmed (to become a low or "0" logic state).
5. Disable the data output loads 4 milliseconds (±25%) after it was enabled.
6. The negative $\overline{PE}$ pulse should rise back to V_{CC} no earlier than the data output loads are disabled.
7. Wait 500 nanoseconds or more.
8. Compare the output data with the desired data.
   a. If any one bit fails to verify, program again starting at step 3. After 8 programming attempts at any one location reject the device as defective. It is acceptable to repulse all desired bits if any one bit does not program.
   b. If all four bits verify apply two more programming pulses (steps 3 thru 7, twice). Then return to step 1 to address and program the next word.

After steps 1 thru 8 are completed for each word to be programmed:

9. Lower all inputs to ground.
10. Lower V_{CC} to +3.5 volts ±.5 volts.
11. Raise $\overline{PE}$ to V_{CC}.*
12. Setup the address of the word to be verified. (High or "1" or V_{IH} inputs must > 2.35 and < 3.8 volts).*
13. Wait 1 microsecond.
14. Compare the output data with the desired data.
    a. If any one bit fails to verify reject the device as defective.
    b. If all four bits verify return to step 12 to verify the next word.



After steps 12 thru 14 are completed for each word in the matrix the device has been properly programmed.

*Never allow any input to rise more than 0.3 volts above V_{CC}.

*OC - Open-Collector
*TS - Three-State
*APU - Active Pull-Up

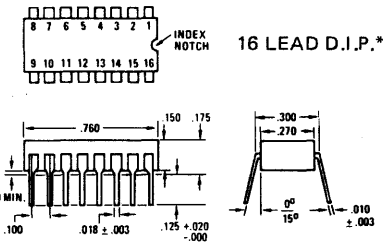
FEATURES

- Common D. C. Electrical Characteristics and Programming Procedure
- Simple, High Speed Programming Procedure (1 Second per 1024 Bits, Typical)
- Expandable - "Open-Collector" or "Three-State" Outputs and Chip Enable Inputs
- Inputs and Outputs TTL Compatible
  - ▶ Low Input Current - 400μA Logic "0", 40μA Logic "1"
  - ▶ Full Output Drive - 16mA Sink, 2mA Source
- Fast Access Time - Guaranteed for Worst Case N^2 Sequencing, Over Commercial and Military Temperature and Voltage Ranges
- Pin Compatible with Industry Standard PROM's and ROM's

DESCRIPTION

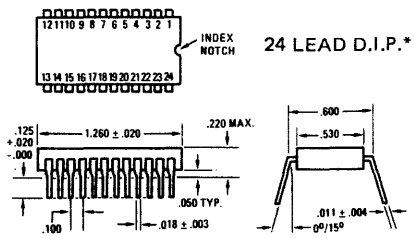
The HM-76XX Generic PROM's comprise a completely compatible family having common D.C. electrical characteristics and identical programming requirements. They are fully decoded, high speed, field programmable ROM's and are available in all commonly used organizations, with both open-collector and three-state outputs. All bits are manufactured storing a logical "1" (outputs high), and can be selectively programmed for a logical "0" (outputs low.)

The nichrome fuse technology is the same as is used in the JAN approved MIL 38510/201 PROM and in all other Harris PROM's.



The field programmable PROM can be custom programmed to any pattern using a simple programming procedure. Schottky Bipolar circuitry provides fast access time, and features temperature and voltage compensation to minimize access time variations.

All pinouts are compatible to industry standard PROM's and ROM's.



In addition to the conventional storage array, extra test rows and columns are included to assure high programmability, and guarantee parametric and A.C. performance. Fuses in these test rows and columns are blown prior to shipment.

ABSOLUTE MAXIMUM RATINGS

Output or Supply Voltage (Operating)	7.0V
Supply Current	650mA
Address/Enable Input Voltage	5.5V
Address/Enable Input Current	-20mA
Output Sink Current	100mA
Storage Temperature	+ 150°C
Operating Temperature (Ambient)	+ 125°C
Maximum Junction Temperature	+ 175°C

Stresses above those listed under the "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and functional operation of the device at these or at any other condition above those indicated in the operational sections of this specification is not implied. (While programming, follow the programming specifications.)

ELECTRICAL CHARACTERSITICS (OPERATING)

HM-76XX-5 (V_{CC}= 5.0V ± 5%, T_A = 0°C to 70°C)

HM-76XX-2, HM-76XX-8 (V_{CC} = 5.0V ± 10%, T_A = -55°C to 125°C)

PROGRAMMING

The Generic PROM's are manufactured with all bits/outputs Logical "1" (Output High). Any desired bit/output can be programmed to a Logical "0" (Output Low) by following the simple procedure shown below. One may build his own programmer to satisfy the specifications described in Table 1, or buy any of the commercially available programmers which meet these specifications. These PROM's can be programmed automatically or by the manual procedure shown below.

PROGRAMMING SPECIFICATIONS

TABLE 1

PARAMETER	SYMBOL	MIN.	RECOMMENDED OR TYP. VALUE	MAX.	UNITS
Address Input Voltage (1)	V_{IH} V_{IL}	2.4 0.0	5.0 0.4	5.0 0.8	V V

Case Temp.	T_C		25	75	°C

1. Address and chip select should not be left open for V_{IH}.
2. Verification at V_{CC} = 4.5 Volts, T_A = 25°C is recommended to guardband performance over full temperature and voltage range.
3. Disable condition will be met with output open circuit.

©IC MASTER 1978

PROGRAMMING PROCEDURE

1. Address the PROM with the binary address of the selected word to be programmed. Address inputs are TTL compatible. An open circuit should not be used to address the PROM.
2. Disable the chip by applying input highs (V_{IH}) to the $\overline{CS}$ input(s). CS inputs (HM-7640/41 only) must remain at V_{IH} for program and verify. The chip select is TTL compatible. An open circuit should not be used to disable the chip. (This step N/A to HM-7644).
3. Disable the programming circuitry by applying an Output Voltage Disable of less than V_{OPD} to the output of the PROM. The output may be left open to achieve the disable.
4. Raise V_{CC} to V_{PH} with rise time equal to t_r.
5. After a delay equal to or greater than t_d, apply a pulse with amplitude of V_{OPE} and duration of t_p to the output selected for programming. Note that the PROM is supplied with fuses intact generating an output high. Programming a fuse will cause the output to go low in the verify mode.
6. Other bits in the same word may be programmed while the V_{CC} input is raised to V_{PH} by applying output enable pulses to each output which is to be programmed. The output enable pulses must be separated by a minimum interval of t_d.
7. Lower V_{CC} to 4.5 Volts following a delay of t_d from the last programming enable pulse applied to an output.
8. Enable the PROM for verification by applying a logic "0" (V_{IL}) to the $\overline{CS}$ input(s).
9. If any bit does not verify as programmed, repeat Steps 2 through 8 until the bit has received a total of 1mSec of programming time. Bits which do not program within 1mSec may be considered programming rejects. Multiple pulses of durations shorter than 1mSec may be used to enhance programming speed.
10. Repeat Steps 1 through 9 for all other bits to be programmed in the PROM.
11. Programming rejects returned to the factory must be accompanied by data giving address and desired and actual output data of a location in which a programming failure has occured.

TYPICAL PROGRAMMING CIRCUIT

The circuit and timing diagrams shown in Figures 1 and 2 will establish the proper programming conditions for the output enable pulses. This allows the use of standard TTL parts for all logic inputs to the PROM. Note the gate which senses the output must be input protected to withstand inputs up to 12.5 Volts during programming.

HM-7610A/11A

256 x 4 PROM

HM-7610A - Open Collector Outputs
HM-7611A - "Three State" Outputs

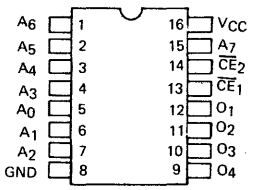
Features

- 40ns MAXIMUM ADDRESS ACCESS TIME
- "THREE STATE" OR OPEN COLLECTOR OUTPUTS
- SIMPLE, HIGH SPEED PROGRAMMING PROCEDURE USING SINGLE PULSES, ASSURES FAST PROGRAMMING AND SUPERIOR RELIABILITY
- INPUTS AND OUTPUTS TTL COMPATIBLE
- FAST ACCESS TIME – GUARANTEED FOR WORST CAST N^2 SEQUENCING OVER COMMERCIAL AND MILITARY TEMPERATURE AND VOLTAGE RANGES.
- INDUSTRYS HIGHEST PROGRAMMING YIELD
- PIN COMPATIBLE WITH INDUSTRY STANDARD PROM's AND ROM's

Description

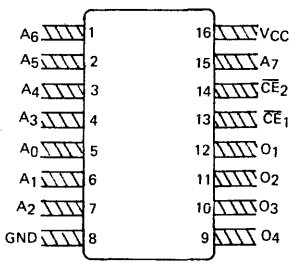
The HM-7610A/11A are fully decoded high speed Schottky TTL 1024-Bit Field Programmable ROMs in a 256 word by 4 bit/word format with open collector (HM-7610A) or "three state" (HM-7611A) outputs. These PROMs are available in 16 pin D.I.P. (ceramic or epoxy) and a 16 pin flatpack.

All bits are manufactured storing a logical "1" (positive logic) and can be selectively programmed for a logical "0" in any bit position.



The HM-7610A/11A contain test rows and columns which are in addition to the storage array to assure high programmability and guarantee parametric and A.C. performance. The fuses in these test rows and columns are blown prior to shipment.

This PROM is intended for use in state of the art ultra high speed logic systems.



Nichrome fuse technology is used on these and all other Harris Bipolar PROM's.

- INDUSTRY'S HIGHEST PROGRAMMING YIELD
- LATCHED OUTPUTS
- INPUT LOADING IS – 100μA, MAXIMUM

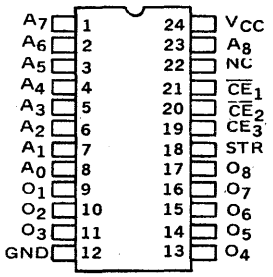
Description

The HM-7640AR/41AR are fully decoded high speed Schottky TTL 4096-Bit Field Programmable ROMs in a 512 word by 8 bit/word format and is available in a 24 pin D.I.P. (ceramic or epoxy) and a 24 pin flatpack.

All bits are manufactured storing a logical "1" (positive logic) and can be selectively programmed for a logical "0" in any bit position.

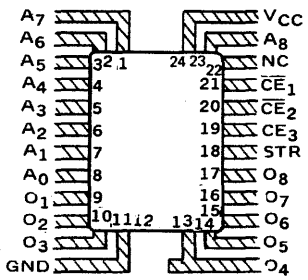
Nichrome fuse technology is used on this and all other Harris Bipolar PROM's.

The HM-7640AR/41AR contain test rows and columns which are in addition to the storage array to assure high programmability and guarantee parametric and A.C. performance. The fuses in these test rows and columns are blown prior to shipment.



There are three chip enable inputs on the HM-7640AR/41AR; $\overline{CE}_1$, $\overline{CE}_2$ low and CE_3 high enables the chip.

HM-7640AR/41AR are operated in the Transparent Read mode by holding the strobe input high throughout the read operation. This is the normal read mode where the three chip enable inputs will control the outputs.



In Latched Read mode, bringing the strobe input low will latch the outputs and chip enable inputs. If the device is disabled, when the strobe input goes low the outputs will be latched in the high impedance state. If the device is in the latched mode the strobe input must be brought high to allow the outputs to respond to new address or chip enable conditions.

Programming

The HM-7640AR/41AR PROMs are manufactured with all bits/outputs logical "1" (output high). Any desired bit/output can be programmed to a logical "0" (output low) by following the simple procedure shown below. One may build his own programmer to satisfy the specifications described in the table, or use any of the commercially available programmers which can meet these specifications. This PROM can be programmed automatically or by the manual procedure shown below.

©IC MASTER 1978

PROGRAMMING SPECIFICATIONS

SYMBOL	PARAMETER	MINIMUM	TYPICAL	MAXIMUM	UNITS
V_{IH} V_{IL}	Address Input Voltage (1)	2.4 0.0	5.0 0.4	5.0 0.8	V V
V_{PH} (2) V_{PL} (3)	Programming/Verify Voltage to V_{CC}	12.0 4.5	12.0 4.5	12.5 5.5	V V
I_{ILP}	Programming Input Low at V_{PH}	–	.250	.500	mA

I_{OPE}	Output Voltage Enable Current	–	–	10.0	mA
TC	Case Temperature	–	25	75	°C

During programming the chip must be disabled for proper operation.

NOTES:
1. No inputs should be left open for V_{IH}.
2. V_{PH} source must be capable of supplying one ampere.
3. It is recommended that dual verification be made at V_{PL} min. and V_{PL} max.
4. Note step 10 in programming procedure.
5. Disable condition will be met with output open circuited.

PROGRAMMING PROCEDURE

1. Address the PROM with the binary address of the word to be programmed. Address inputs are TTL compatible. An open circuit should not be used to address the PROM.

2. Bring the $\overline{CE}_1$ and $\overline{CE}_2$ inputs high and the CE_3 input low to disable the device. The deselecting of the device during programming is an essential step in correctly programming this and all other Harris PROM's. The chip enables are TTL compatible. An open circuit should not be used to disable the chip.

3. Apply a logical "1" to the strobe input to place the chip in transparent read mode which is essential during programming. The strobe must remain high throughout the entire programming procedure.

4. Disable the programming circuitry by applying a voltage disable of V_{OPD} to the outputs of the PROM. The output may be left open to achieve the disable.

5. Raise V_{CC} to V_{PH} with rise time equal to t_r.

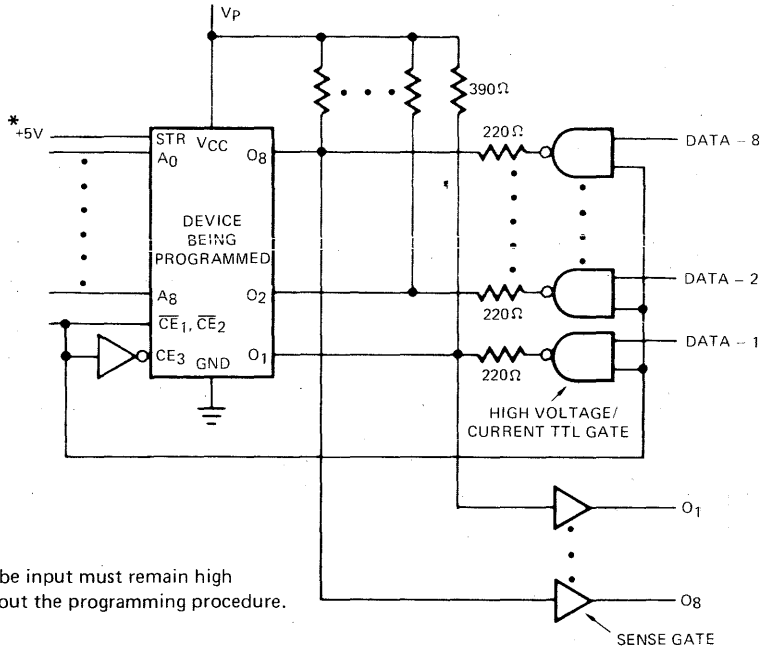
6. After a delay equal to or greater than t_d, apply a pulse with amplitude of V_{OPE} and duration of t_p to the output selected for programming. Note that the PROM is supplied with fuses intact generating an output high. Programming a fuse will cause the output to go low in the verify mode.

7. Other bits in the same word may be programmed while the V_{CC} input is raised to V_{PH} by applying output enable pulses to each output which is to be programmed. The output enable pulses must be separated by a minimum interval of t_d.

8. Lower V_{CC} to 4.5 volts following a delay of t_d from the last programming enable pulse applied to an output.

9. Enable the PROM for verification by applying a logic "0" to $\overline{CE}_1$ and $\overline{CE}_2$ and a logic "1" to CE_3. Repeat verification at V_{CC} = 5.5 volts.

10. If any bit does not verify as programmed, repeat steps 2 through 9 until the bit has received a total of 1mSec. of programming time. Bits which do not program within 1mSec. are programming rejects. No further attempt to program these parts should be made.



11. Repeat steps 1 through 10 for all other bits to be programmed in the PROM.

12. Programming rejects returned to the factory must be accompanied by data giving address, desired, and actual output data of a location in which a programming failure has occurred.

TYPICAL PROGRAMMING CIRCUIT

The circuit and timing diagrams shown in Figures 1 and 2 will establish the proper programming conditions for the output enable pulses. This allows the use of standard TTL parts for all logic inputs to the PROM. Note the gate which senses the output must withstand inputs up to 12.5 volts during programming.

©IC MASTER 1978

*NOTE: The strobe input must remain high throughout the programming procedure.

FIGURE 1

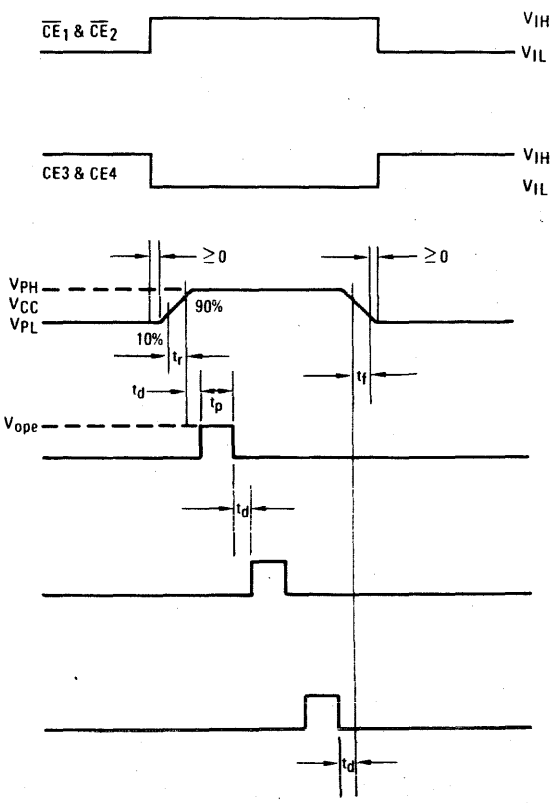


FIGURE 2

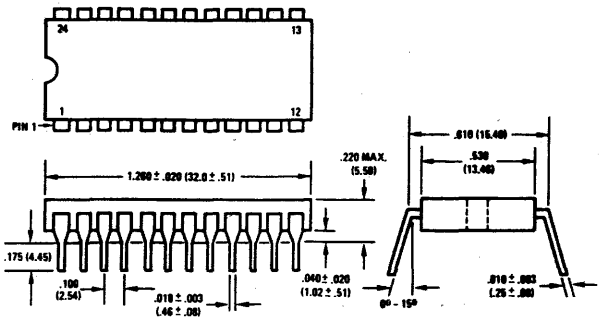

NOTE: The strobe input must remain high throughout the programming procedure. This timing diagram shows device terminal conditions. Each positive going data pulse at the terminal blows the corresponding bit resulting in a low output in that bit, therefore a low input at the DATA-X points of the Figure 1 circuit results in a permanent low output of a bit.

HM-7647R

512 x 8 PROM

Features

- 60ns MAXIMUM ADDRESS ACCESS TIME
- "THREE STATE" OUTPUTS WITH TWO CHIP ENABLE INPUTS
- SIMPLE HIGH SPEED PROGRAMMING PROCEDURE – ONE PULSE/BIT. ASSURES FAST PROGRAMMING AND SUPERIOR RELIABILITY.
- FAST ACCESS TIME – GUARANTEED FOR WORST CASE N^2 SEQUENCING OVER COMMERCIAL AND MILITARY TEMPERATURE AND VOLTAGE RANGES.
- INDUSTRY'S HIGHEST PROGRAMMING YIELD
- PIN COMPATIBLE WITH THE 82S115
- LATCHED OUTPUTS
- INPUT LOADING IS – 100 μA MAXIMUM

Description

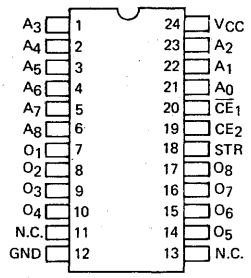
The HM-7647R is a fully decoded high speed Schottky TTL 4096-Bit Field Programmable ROM in a 512 word by 8 bit/word format and is available in a 24 pin D.I.P. (ceramic or epoxy) and a 24 pin flatpack.

All bits are manufactured storing a logical "1" (positive logic) and can be selectively programmed for a logical "0" in any bit position. The HM-7647R has three state outputs.

Nichrome fuse technology is used on this and all other Harris Bipolar PROM's.

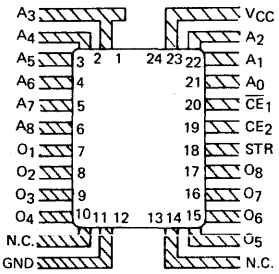
The pinout is identical to the 82S115 PROM.

The HM-7647R contains test rows and columns which are in addition to the storage array to assure high programmability and guarantee parametric and A. C. performance. The fuses in these test rows and columns are blown prior to shipment.



There are two chip enable inputs on the HM-7647R. $\overline{CE}_1$ low and CE_2 high enables the chip.

HM-7647R is operated in the Transparent Read mode by holding the strobe input high throughout the read operation. This is the normal read mode where the two chip enable inputs will control the outputs.



In Latched Read mode, bringing the strobe input low will latch the outputs and chip enable inputs. If the device is disabled, when the strobe input goes low the outputs will be latched in the high impedance state. If the device is in the latched mode the strobe input must be brought high to allow the outputs to respond to new address or chip enable conditions.

During programming the chip must be disabled for proper operation.

NOTES:
1. No inputs should be left open for V_{IH}.
2. V_{PH} source must be capable for supplying one ampere.
3. It is recommended that dual verification be made at V_{PL} min. and V_{PL} max.
4. Note step 10 in programming procedure.
5. Disable condition will be met with output open circuited.

PROGRAMMING PROCEDURE

1. Address the PROM with the binary address of the word to be programmed. Address inputs are TTL compatible. An open circuit should not be used to address the PROM.

2. Bring the $\overline{CE}_1$ input high and the CE_2 input low to disable the device. The deselecting of the device during programming is an essential step in correctly programming this and all other Harris PROM's. The chip enables are TTL compatible. An open circuit should not be used to disable the chip.

3. Apply a logical "1" to the strobe input to place the chip in transparent read mode which is essential during programming. The strobe must remain high throughout the entire programming procedure.

4. Disable the programming circuitry by applying a voltage disable of V_{OPD} to the outputs of the PROM. The output may be left open to achieve the disable.

5. Raise V_{CC} to V_{PH} with rise time equal to t_r.

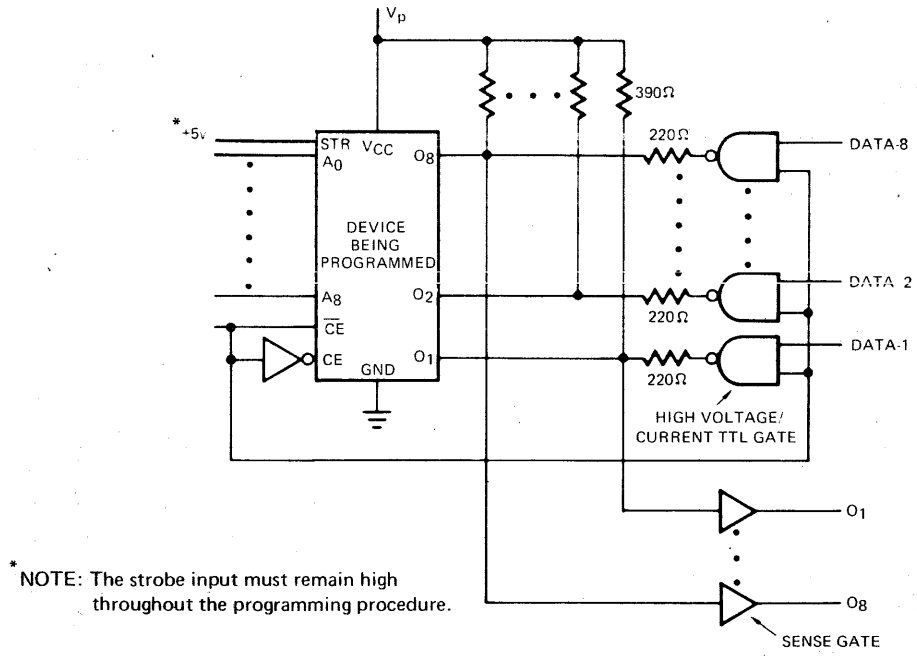
6. After a delay equal to or greater than t_d, apply a pulse with amplitude of V_{OPE} and duration of t_p to the output selected for programming. Note that the PROM is supplied with fuses intact generating an output high. Programming a fuse will cause the output to go low in the verify mode.

7. Other bits in the same word may be programmed while the V_{CC} input is raised to V_{PH} by applying output enable pulses to each output which is to be programmed. The output enable pulses must be separated by a minimum interval of t_d.

8. Lower V_{CC} to 4.5 volts following a delay of t_d from the last programming enable pulse applied to an output.

9. Enable the PROM for verification by applying a logic "0" to $\overline{CE}_1$ and a logic "1" to CE_2. Repeat verification at V_{CC} = 5.5 volts.

10. If any bit does not verify as programmed, repeat steps 2 through 9 until the bit has received a total of 1mSec. of programming time. Bits which do not program within 1mSec. are programming rejects. No further attempt to program these parts should be made.



11. Repeat steps 1 through 10 for all other bits to be programmed in the PROM.

12. Programming rejects returned to the factory must be accompanied by data giving address, desired, and actual output data of a location in which a programming failure has occurred.

TYPICAL PROGRAMMING CIRCUIT

The circuit and timing diagrams shown in Figures 1 and 2 will establish the proper programming conditions for the output enable pulses. This allows the use of standard TTL parts for all logic inputs to the PROM. Note the gate which senses the output must withstand inputs up to 12.5 volts during programming.

©IC MASTER 1978

*NOTE: The strobe input must remain high throughout the programming procedure.

FIGURE 1

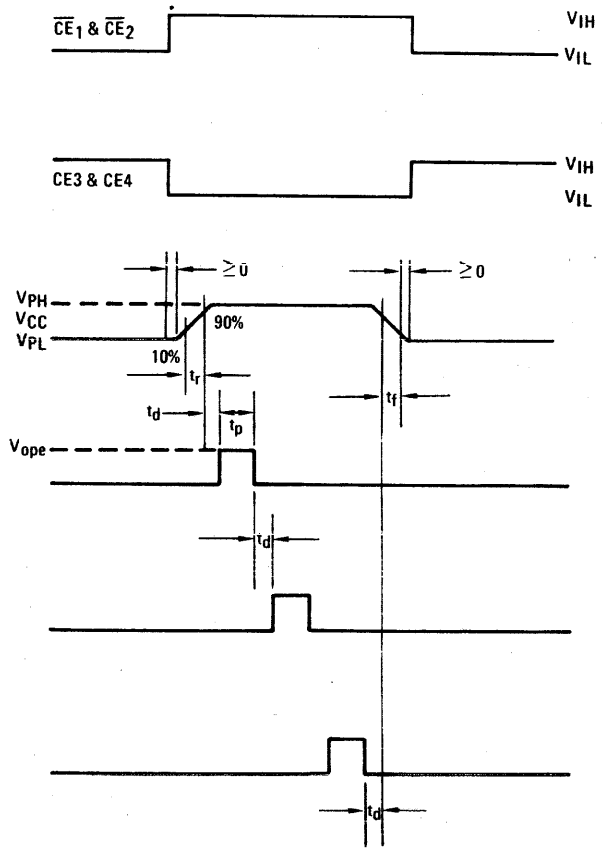


FIGURE 2

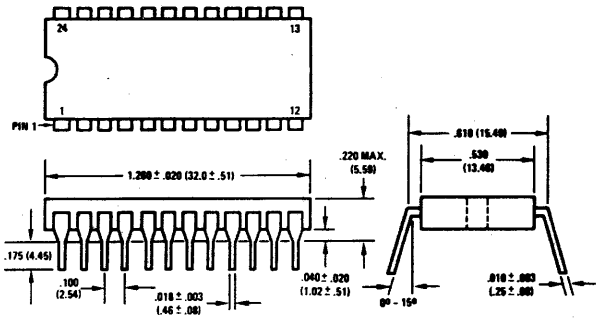
The strobe input must remain high throughout the programming procedure.



This timing diagram shows device terminal conditions. Each positive going data pulse at the terminal blows the corresponding bit resulting in a low output in that bit, therefore a low input at the DATA-X points of the Figure 1 circuit results in a permanent low output of a bit.

Description

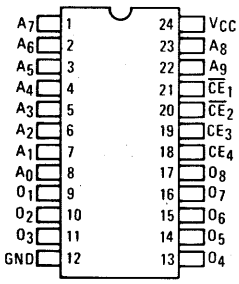
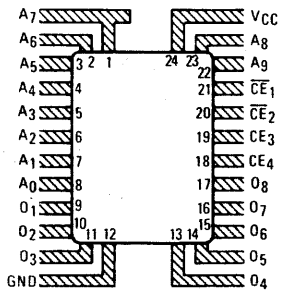
The HM-7680/81 is a fully decoded high speed Schottky TTL 8192/Bit Field Programmable ROM in a 1K word by 8 bit/word format with open collector (HM-7680) or "Three-State" (HM-7681) outputs. These PROM's are available in a 24 pin D.I.P. (ceramic or epoxy) and a 24 pin flat pack.

All bits are manufactured storing a logical "1" (Positive Logic) and can be selectively programmed for a logical "0" in any one bit position.



Nichrome fuse technology is used on this and all other Harris Bipolar PROMs.

The HM-7680/81 contains test rows and columns which are in addition to the storage array to assure high programmability and guarantee parametric and A.C. performance. The fuses in these test rows and columns are blown prior to shipment.



There are four chip enable inputs on the HM-7680/81. $\overline{CE}_1$, $\overline{CE}_2$ low, and CE_3, CE_4 high enables the chip.

A.C. TEST LOAD

Programming

The HM-7680/81 PROM is manufactured with all bits/outputs logical "1" (output high). Any desired bit/output can be programmed to a logical "0" (output low) by following the simple procedure shown below. One may build his own programmer to satisfy the specifications described in the table, or use any of the commercially available programmers which can meet these specifications. This PROM can be programmed automatically or by the manual procedure shown below.

PROGRAMMING SPECIFICATIONS

SYMBOL	PARAMETER	MINIMUM	TYPICAL	MAXIMUM	UNITS
V_{IH} V_{IL}	Address Input Voltage (1)	2.4 0.0	5.0 0.4	5.0 0.8	V V
V_{PH} (2) V_{PL} (3)	Programming/Verify Voltage to V_{CC}	12.0 4.5	12.0 4.5	12.5 5.5	V V
I_{ILP}	Programming Input Low at V_{PH}	–	.250	.500	mA
tr tf	Programming (V_{CC}) Voltage Rise and Fall Time	1.0 1.0	1.0 1.0	10.0 10.0	µs µs
td	Programming Delay	10	10	100	µs
tp	Programming Pulse Width (4)	90	100	110	µs
D.C.	Programming Duty Cycle	–	50	90	%
V_{OPE} V_{OPD}	Output Voltage Enable (5) Disable	10.5 4.5	10.5 5.0	11.0 5.5	V V
I_{OPE}	Output Voltage Enable Current	–	–	10.0	mA
TC	Case Temperature	–	25	75	°C

During programming the chip must be disabled for proper operation.

NOTES:
1. No inputs should be left open for V_{IH}.
2. V_{PH} source must be capable for supplying one ampere.
3. It is recommended that dual verification be made at V_{PL} min. and V_{PL} max.
4. Note step 9 in programming procedure.
5. Disable condition will be met with output open circuited.

©IC MASTER 1978

PROGRAMMING PROCEDURE

1. Address the PROM with the binary address of the word to be programmed. Address inputs are TTL compatible. An open circuit should not be used to address the PROM.

2. Bring the $\overline{CE}_1$ and $\overline{CE}_2$ inputs high and the CE_3 and CE_4 inputs low to disable the device. The deselecting of the device during programming is an essential step in correctly programming this and all other Harris PROM's. The chip enables are TTL compatible. An open circuit should not be used to disable the chip.

3. Disable the programming circuitry by applying a voltage disable of V_{OPD} to the outputs of the PROM. The output may be left open to achieve the disable.

4. Raise V_{CC} to V_{PH} with rise time equal to t_r.

5. After a delay equal to or greater than t_d, apply a pulse with amplitude of V_{OPE} and duration of t_p to the output selected for programming. Note that the PROM is supplied with fuses intact generating an output high. Programming a fuse will cause the output to go low in the verify mode.

6. Other bits in the same word may be programmed while the V_{CC} input is raised to V_{PH} by applying output enable pulses to each output which is to be programmed. The output enable pulses must be separated by a minimum interval of t_d.

7. Lower V_{CC} to 4.5 volts following a delay of t_d from the last programming enable pulse applied to an output.

8. Enable the PROM for verification by applying a logic "0" to $\overline{CE}_1$ and $\overline{CE}_2$ and a logic "1" to CE_3 and CE_4. Repeat verification at V_{CC} = 5.5 volts.

9. If any bit does not verify as programmed, repeat steps 2 through 8 until the bit has received a total of 1msec of programming time. Bits which do not program within 1msec are programming rejects. No further attempt to program these parts should be made.

10. Repeat steps 1 through 9 for all other bits to be programmed in the PROM.

11. Programming rejects returned to the factory must be accompanied by data giving address, desired, and actual output data of a location in which a programming failure has occured.

TYPICAL PROGRAMMING CIRCUIT

The circuit and timing diagrams shown in Figures 1 and 2 will establish the proper programming conditions for the output enable pulses. This allows the use of standard TTL parts for all logic inputs to the PROM. Note the gate which senses the output must withstand inputs up to 12.5 volts during programming.

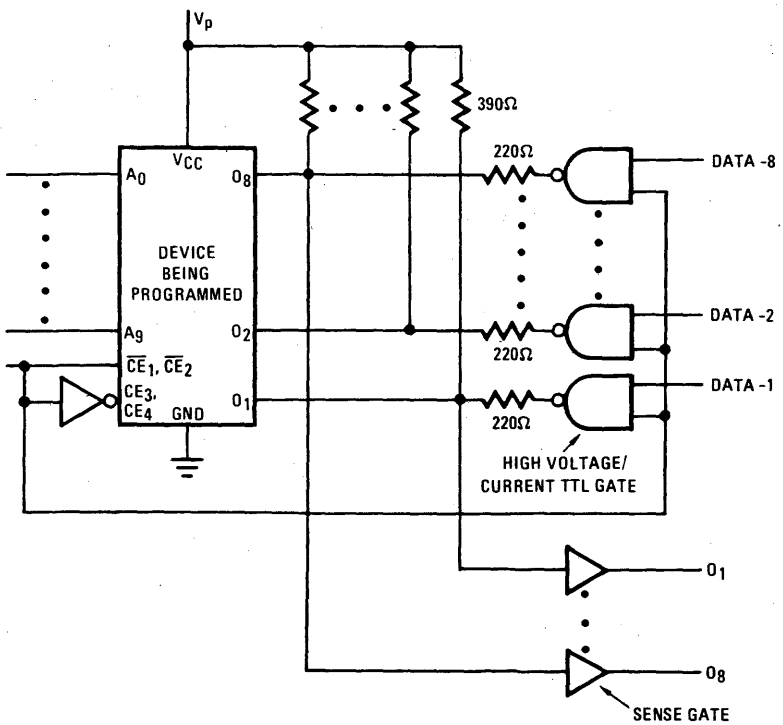

FIGURE 1

©IC MASTER 1978

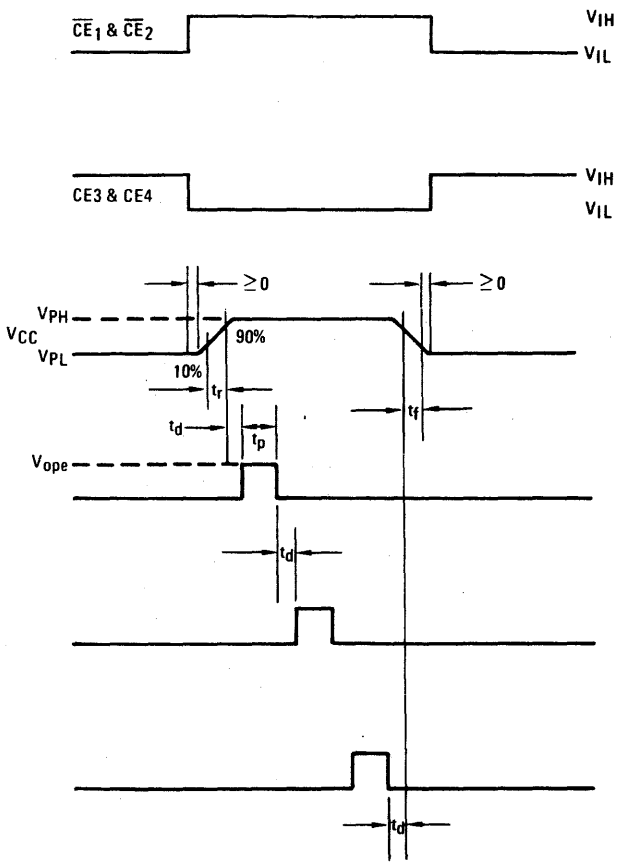

FIGURE 2

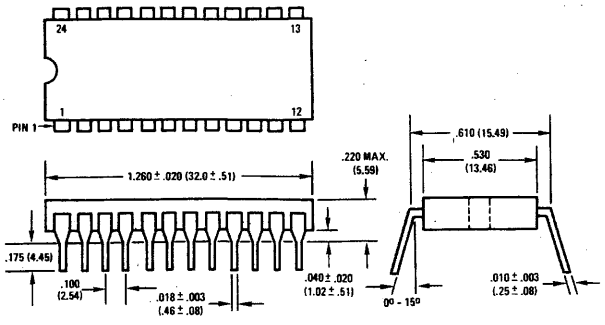

This timing diagram shows device terminal conditions. Each positive going data pulse at the terminal blows the corresponding bit, resulting in a low output for that bit. Therefore, a low input at the DATA-X points of the Figure 1 circuit results in a permanent low output of a bit.

Preliminary

HM-7680R/81R
1K x 8 PROM

HM-7680R - Open Collector Outputs
HM-7681R - "Three State" Outputs

Features

- 60ns MAXIMUM ADDRESS ACCESS TIME
- "THREE STATE" OR OPEN COLLECTOR OUTPUTS AND THREE CHIP ENABLE INPUTS
- SIMPLE HIGH SPEED PROGRAMMING PROCEDURE – ONE PULSE/BIT. ASSURES FAST PROGRAMMING AND SUPERIOR RELIABILITY
- FAST ACCESS TIME – GUARANTEED FOR WORST CASE N^2 SEQUENCING OVER COMMERCIAL AND MILITARY TEMPERATURES AND VOLTAGE RANGES
- INDUSTRY'S HIGHEST PROGRAMMING YIELD
- LATCHED OUTPUTS

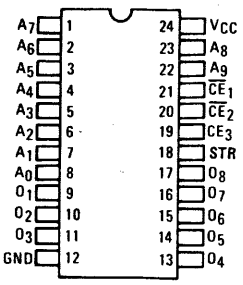
Description

The HM-7680R/81R is a fully decoded high speed Schottky TTL 8192-Bit Field Programmable ROM in a 1K word by 8 bit/word format with open collector (HM-7680R) or "Three State" (HM-7681R) outputs. These PROMs are available in a 24 pin D.I.P. (ceramic or epoxy) and a 24 pin flatpack.

All bits are manufactured storing a logical "1" (positive logic) and can be selectively programmed for a logical "0" in any bit position.

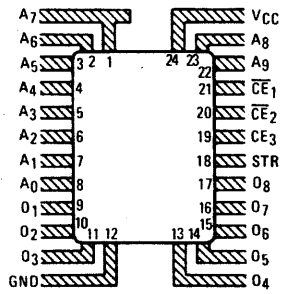
Nichrome fuse technology is used on these and all other Harris Bipolar PROM's.

The HM-7680R/81R contains test rows and columns which are in addition to the storage array to assure high programmability and guarantee parametric and A.C. performance. The fuses in these test rows and columns are blown prior to shipment.



There are three chip enable inputs on the HM-7680R/81R. $\overline{CE}_1$, $\overline{CE}_2$ low and CE_3 high enables the chip.

The HM-7680R/81R is operated in the Transparent Read mode by holding the strobe input high throughout the read operation. This is the normal read mode where the three chip enable inputs will control the outputs.



In Latched Read mode, bringing the strobe input low will latch the outputs and chip enable inputs. If the device is disabled when the strobe input is low, the outputs will be latched in the high impedance state. If the device is in the latched mode the strobe input must be brought high to allow the outputs to respond to new address or chip enable conditions.

During programming the chip must be disabled for proper operation.

NOTES:
1. No inputs should be left open for V_{IH}.
2. V_{PH} source must be capable for supplying one ampere.
3. It is recommended that dual verification be made at V_{PL} min. and V_{PL} max.
4. Note step 10 in programming procedure.
5. Disable condition will be met with output open circuited.

PROGRAMMING PROCEDURE

1. Address the PROM with the binary address of the word to be programmed. Address inputs are TTL compatible. An open circuit should not be used to address the PROM.

2. Bring the $\overline{CE}_1$ and $\overline{CE}_2$ inputs high and the CE_3 inputs low to disable the device. The deselecting of the device during programming is an essential step in correctly programming this and all other Harris PROM's. The chip enables are TTL compatible. An open circuit should not be used to disable the chip.

3. Apply a logical "1" to the strobe input to place the chip in transparent read mode which is essential during programming. The strobe must remain high throughout the entire programming procedure.

4. Disable the programming circuitry by applying a voltage disable of V_{OPD} to the outputs of the PROM. The output may be left open to achieve the disable.

5. Raise V_{CC} to V_{PH} with rise time equal to t_r.

6. After a delay equal to or greater than t_d, apply a pulse with amplitude of V_{OPE} and duration of t_p to the output selected for programming. Note that the PROM is supplied with fuses intact generating an output high. Programming a fuse will cause the output to go low in the verify mode.

7. Other bits in the same word may be programmed while the V_{CC} input is raised to V_{PH} by applying output enable pulses to each output which is to be programmed. The output enable pulses must be separated by a minimum interval of t_d.

8. Lower V_{CC} to 4.5 volts following a delay of t_d from the last programming enable pulse applied to an output.

9. Enable the PROM for verification by applying a logic "0" to $\overline{CE}_1$ and $\overline{CE}_2$ and a logic "1" to CE_3. Repeat verification at V_{CC} = 5.5 volts.

10. If any bit does not verify as programmed, repeat steps 2 through 9 until the bit has received a total of 1msec of programming time. Bits which do not program within 1msec are programming rejects. No further attempt to program these parts should be made.

11. Repeat steps 1 through 10 for all other bits to be programmed in the PROM.

12. Programming rejects returned to the factory must be accompanied by data giving address, desired, and actual output data of a location in which a programming failure has occured.

TYPICAL PROGRAMMING CIRCUIT

The circuit and timing diagrams shown in Figures 1 and 2 will establish the proper programming conditions for the output enable pulses. This allows the use of standard TTL parts for all logic inputs to the PROM. Note the gate which senses the output must withstand inputs up to 12.5 volts during programming.

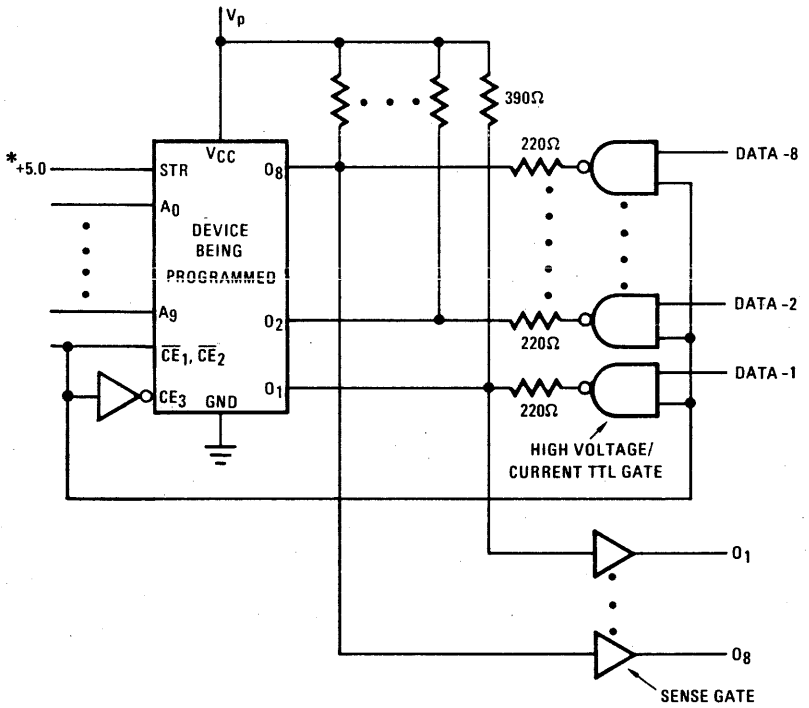

FIGURE 1

*The Strobe Input must remain high throughout the programming procedure.

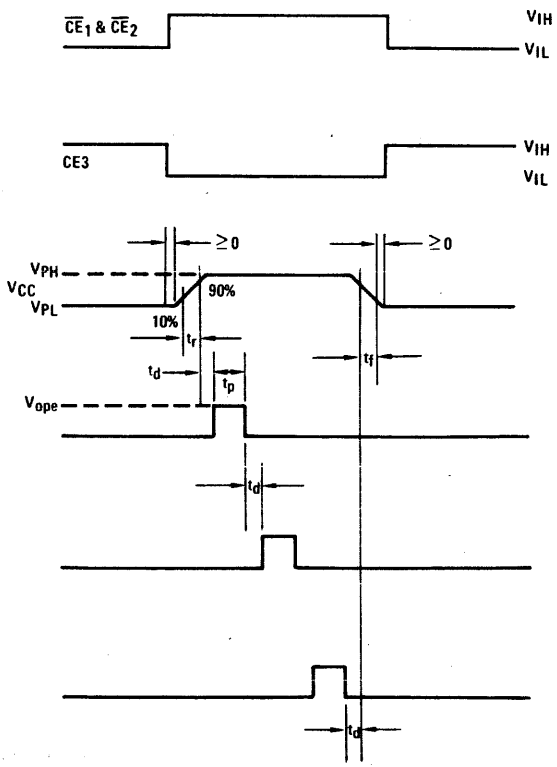

FIGURE 2

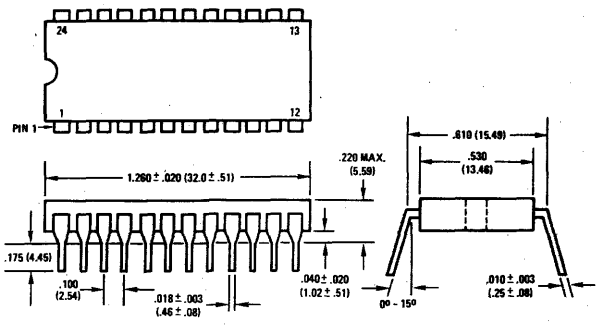
The Strobe Input must remain high throughout the programming procedure.



This timing diagram shows device terminal conditions. Each positive going data pulse at the terminal blows the corresponding bit, resulting in a low output for that bit. Therefore, a low input at the DATA-X points of the Figure 1 circuit results in a permanent low output of a bit.

HM-7680RP/81RP

Preliminary 1K x 8 PROM

HM-7680RP - Open Collector Outputs
HM-7681RP - "Three State" Outputs

Features

- 60ns MAXIMUM ADDRESS ACCESS TIME
- "THREE STATE" OR OPEN COLLECTOR OUTPUTS AND TWO CHIP ENABLE INPUTS.
- SIMPLE HIGH SPEED PROGRAMMING PROCEDURE – ONE PULSE/BIT. ASSURES FAST PROGRAMMING AND SUPERIOR RELIABILITY.
- FAST ACCESS TIME – GUARANTEED FOR WORST CASE N^2 SEQUENCING OVER COMMERCIAL AND MILITARY TEMPERATURE AND VOLTAGE RANGES.
- INDUSTRY'S HIGHEST PROGRAMMING YIELD.
- LATCHED OUTPUTS.
- A POWER DOWN INPUT ALLOWING 70% REDUCTION IN NOMINAL POWER DISSIPATION.

Description

The HM-7680RP/81RP are fully decoded high speed Schottky TTL 8192-Bit Field Programmable ROM's in a 1K word by 8 bit/word format with open collector (HM-7680RP) or "three state." (HM-7681RP) outputs. These PROM's are available in a 24 pin D.I.P. (ceramic or epoxy) and a 24 pin flatpack.

All bits are manufactured storing a logical "1" (positive logic) and can be selectively programmed for a logical "0" in any bit position.

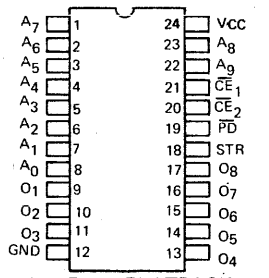
Nichrome fuse technology is used on these and all other Harris Bipolar PROM's.

The HM-7680RP/81RP contain test rows and columns which are in addition to the storage array to assure high programmability and guarantee parametric and A.C. performance. The fuses in these test rows and columns are blown prior to shipment.

There are two chip enable inputs on the HM-7680RP/81RP. $\overline{CE}_1$, $\overline{CE}_2$ low enables the device.

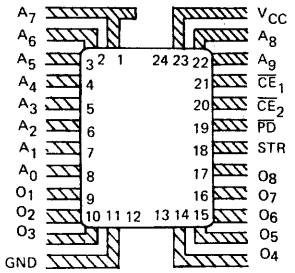
There is a power down input on this device. A powered down chip has a 70% reduction in power dissipation if the outputs are not latched and a 50% reduction in power if the outputs are latched.

The HM-7680RP/81RP is operated in the Transparent Read mode by holding the strobe input high and the $\overline{PD}$ input high throughout the read operation. This is the normal read mode where the two chip enables and the power down inputs will control the outputs.



In Latched Read mode, bringing the strobe input low will latch the outputs and the chip enable inputs. However, the power down input is independent of the latched function and can be changed while in the latched mode. If the device is disabled when the strobe input goes low, the outputs will be latched in the high impedance state. If the device is in the latched mode the strobe input must be brought high to allow the outputs to respond to new address or chip enable conditions.

The following is a summary of the functional dependencies of the operating modes:



1. Chip enabled, transparent, power up – normal mode where the power down input is effectively a chip enable.
2. Chip enabled, latched, power up – this is normal latched mode where the output remains latched regardless of address and chip enable switching.
3. Chip enabled, latched, power down – this is the powered down latched mode where the output data ramains latched while power is reduced to 50% of its normal value. If the latch strobe changes state while in this mode, the outputs will go to a high impedance state and power will reduce to 30% of nominal power.
4. Chip disabled, transparent, power down – this is the normal powered down mode where the outputs are in a high impedance state and the power is reduced to 30% of the nominal power.

Following is a table to clarify the operational interdependencies.

HARRIS SEMICONDUCTOR PRODUCTS DIVISION

Preliminary

HM-7608

1K x 8 PROM

Features

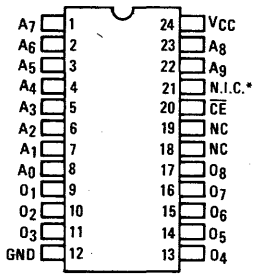
- 60ns MAXIMUM ADDRESS ACCESS TIME
- "THREE-STATE" OUTPUTS WITH A CHIP ENABLE INPUT
- SIMPLE, HIGH SPEED PROGRAMMING PROCEDURE – ONE PULSE/BIT. ASSURES FAST PROGRAMMING AND SUPERIOR RELIABILITY.
- FAST ACCESS TIME – GUARANTEED FOR WORST CASE N^2 SEQUENCING OVER COMMERCIAL AND MILITARY TEMPERATURE AND VOLTAGE RANGES.
- INDUSTRY'S HIGHEST PROGRAMMING YIELD
- PIN COMPATIBLE WITH THE 2708 WITH:
  - ONLY ONE 5 VOLT SUPPLY
  - SUPERIOR ACCESS TIME
  - FASTER PROGRAMMING TIME

Description

The HM-7608 is a fully decoded high speed Schottky TTL 8192-Bit Field Programmable ROM in a 1K word by 8 bit/word format and is available in a 24 pin D.I.P. (ceramic or epoxy) and a 24 pin flat pack.

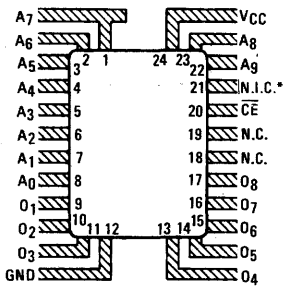
All bits are manufactured storing a logical "1" (Positive Logic) and can be selectively programmed for a logical "0" in any bit position, the HM-7608 has three-state outputs.

Nichrome fuse technology is used on this and all other Harris Bipolar PROM's.



The HM-7608 contains test rows and columns which are in addition to the storage array to assure high programmability and guarantee parametric and A.C. performance. The fuses in these test rows and columns are blown prior to shipment.

This PROM is a plug in replacement for the 2708 where the V_{SS} pin on the 2708 becomes GND on the HM-7608. The V_{BB}, VDD, and program pins on the 2708 are all N.C. on the HM-7608.



There is a chip enable input on the HM-7608 where $\overline{CE}$ low enables the device.

A.C. TEST LOAD

Programming

The HM-7608 PROM is manufactured with all bits/outputs logical "1" (output high). Any desired bit/output can be programmed to a logical "0" (output low) by following the simple procedure shown below. One may build his own programmer to satisfy the specifications described in the table, or use any of the commercially available programmers which can meet these specifications. This PROM can be programmed automatically or by the manual procedure shown below.

PROGRAMMING SPECIFICATIONS

SYMBOL	PARAMETER	MINIMUM	TYPICAL	MAXIMUM	UNITS
V_{IH} V_{IL}	Address Input Voltage (1)	2.4 0.0	5.0 0.4	5.0 0.8	V V
V_{PH} (2) V_{PL} (3)	Programming/Verify Voltage to V_{CC}	12.0 4.5	12.0 4.5	12.5 5.5	V V
I_{ILP}	Programming Input Low at V_{PH}	–	.250	.500	mA
tr tf	Programming (V_{CC}) Voltage Rise and Fall Time	1.0 1.0	1.0 1.0	10.0 10.0	µs µs
td	Programming Delay	10	10	100	µs
tp	Programming Pulse Width (4)	90	100	110	µs
D.C.	Programming Duty Cycle	–	50	90	%
V_{OPE} V_{OPD}	Output Voltage Enable (5) Disable	10.5 4.5	10.5 5.0	11.0 5.5	V V
I_{OPE}	Output Voltage Enable Current	–	–	10.0	mA
TC	Case Temperature	–	25	75	°C

During programming the chip must be disabled for proper operation.

NOTES:
1. No inputs should be left open for V_{IH}.
2. V_{PH} source must be capable for supplying one ampere.
3. It is recommended that dual verification be made at V_{PL} min. and V_{PL} max.
4. Note step 9 in programming procedure.
5. Disable condition will be met with output open circuited.

©IC MASTER 1978

PROGRAMMING PROCEDURE

1. Address the PROM with the binary address of the word to be programmed. Address inputs are TTL compatible. An open circuit should not be used to address the PROM.

2. Bring the $\overline{CE}$ input high to disable the device. The deselecting of the device during programming is an essential step in correctly programming this and all other Harris PROM's. The chip enable is TTL compatible. An open circuit should not be used to disable the chip.

3. Disable the programming circuitry by applying a voltage disable of V_{OPD} to the outputs of the PROM. The output may be left open to achieve the disable.

4. Raise V_{CC} to V_{PH} with rise time equal to t_r.

5. After a delay equal to or greater than t_d, apply a pulse with amplitude of V_{OPE} and duration of t_p to the output selected for programming. Note that the PROM is supplied with fuses intact generating an output high. Programming a fuse will cause the output to go low in the verify mode.

6. Other bits in the same word may be programmed while the V_{CC} input is raised to V_{PH} by applying output enable pulses to each output which is to be programmed. The output enable pulses must be separated by a minimum interval of t_d.

7. Lower V_{CC} to 4.5 volts following a delay of t_d from the last programming enable pulse applied to an output.

8. Enable the PROM for verification by applying a logic "0" to $\overline{CE}$. Repeat verification at V_{CC} = 5.5 volts.

9. If any bit does not verify as programmed, repeat steps 2 through 8 until the bit has received a total of 1msec of programming time. Bits which do not program within 1msec are programming rejects. No further attempt to program these parts should be made.

10. Repeat steps 1 through 9 for all other bits to be programmed in the PROM.

11. Programming rejects returned to the factory must be accompanied by data giving address, desired, and actual output data of a location in which a programming failure has occured.

TYPICAL PROGRAMMING CIRCUIT

The circuit and timing diagrams shown in Figures 1 and 2 will establish the proper programming conditions for the output enable pulses. This allows the use of standard TTL parts for all logic inputs to the PROM. Note the gate which senses the output must withstand inputs up to 12.5 volts during programming.

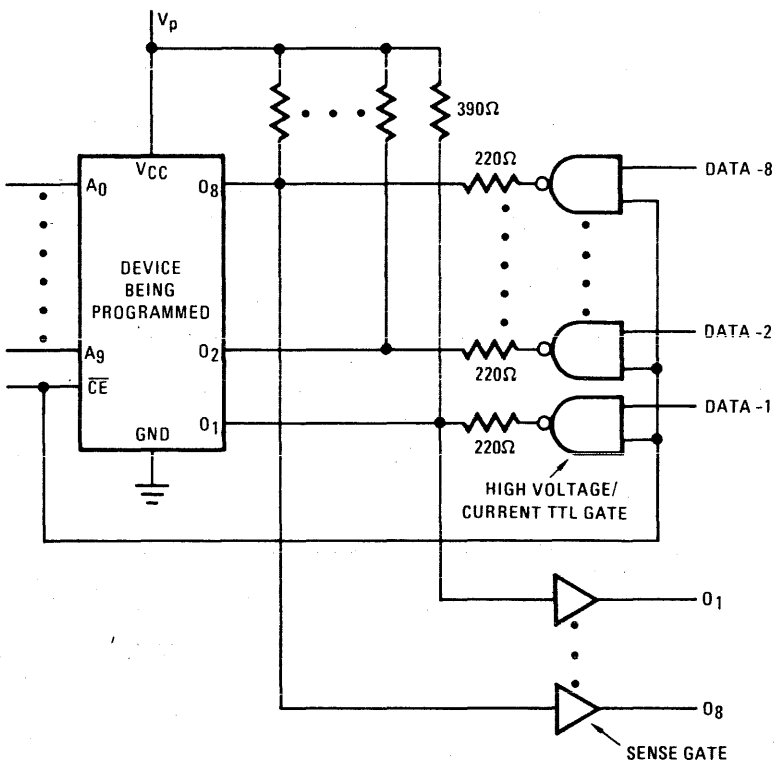

FIGURE 1

©IC MASTER 1978

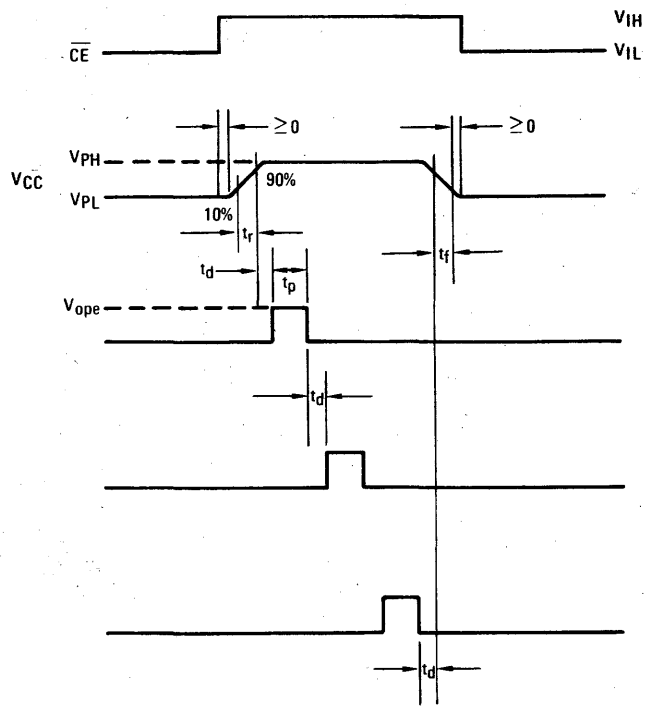

FIGURE 2

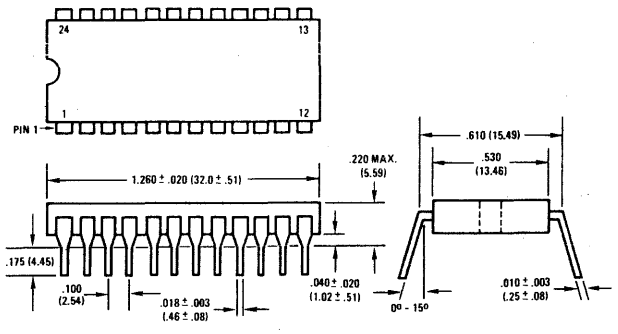

This timing diagram shows device terminal conditions. Each positive going data pulse at the terminal blows the corresponding bit, resulting in a low output for that bit. Therefore, a low input at the DATA-X points of the Figure 1 circuit results in a permanent low output of a bit.

HARRIS SEMICONDUCTOR PRODUCTS DIVISION

HM-7686RP/87RP

Preliminary

2K x 4 PROM

HM-7686RP - Open Collector Outputs
HM-7687RP - "Three State" Outputs

Features

- 80ns MAXIMUM ADDRESS ACCESS TIME
- "THREE STATE" OR OPEN COLLECTOR OUTPUTS AND A CHIP ENABLE INPUT.
- SIMPLE HIGH SPEED PROGRAMMING PROCEDURE – ONE PULSE/BIT. ASSURES FAST PROGRAMMING AND SUPERIOR RELIABILITY.
- FAST ACCESS TIME – GUARANTEED FOR WORST CASE N^2 SEQUENCING OVER COMMERCIAL AND MILITARY TEMPERATURE AND VOLTAGE RANGES.
- INDUSTRY'S HIGHEST PROGRAMMING YIELD.
- LATCHED OUTPUTS.
- A POWER DOWN INPUT ALLOWING 70% REDUCTION IN NOMINAL POWER DISSIPATION.

Description

The HM-7686RP/87RP are fully decoded high speed Schottky TTL 8192-Bit Field Programmable ROM's in a 2K word by 4 bit/word format with open collector (HM-7686RP) or "three state " (HM-7687RP) outputs. These PROM's are available in a 20 pin D.I.P. (ceramic or epoxy) and a 20 pin flatpack.

All bits are manufactured storing a logical "1" (positive logic) and can be selectively programmed for a logical "0" in any bit position.

Nichrome fuse technology is used on these and all other Harris Bipolar PROM's.

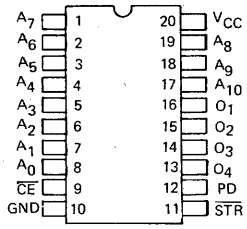
The HM-7686RP/87RP contain test rows and columns which are in addition to the storage array to assure high programmability and guarantee parametric and A.C. performance. The fuses in these test rows and columns are blown prior to shipment.

There is a chip enable input on the HM-7686RP/87RP. $\overline{CE}$ low enables the device.

There is a power down input on this device. A powered down chip has a 70% reduction in power dissipation if the outputs are not latched and a 50% reduction in power if the outputs are latched.

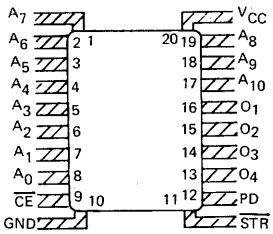
The HM-7686RP/87RP is operated in the Transparent Read mode by holding the strobe input low and the PD input low throughout the read operation. This is the normal read mode where the chip enable and the power down input will control the outputs.

In Latched Read mode, bringing the strobe input high will latch the outputs and the chip enable inputs. However, the power down input is independent of the latched function and can be changed while in the latched mode. If the device is disabled when the strobe input goes high, the outputs will be latched in the high impedance state. If the device is in the latched mode the strobe input must be brought low to allow the outputs to respond to new address or chip enable conditions.



The following is a summary of the functional dependencies of the operating modes:

1. Chip enabled, transparent, power up – normal mode where the power down input is effectively a chip enable.
2. Chip enabled, latched, power up – this is normal latched mode where the output remains latched regardless of address and chip enable switching.
3. Chip enabled, latched, power down – this is the powered down latched mode where the output data remains latched while power is reduced to 50% of its normal value. If the latch strobe changes state while in this mode, the outputs will go to a high impedance state and power will reduce to 30% of nominal power.
4. Chip disabled, transparent, power down – this is the normal powered down mode where the outputs are in a high impedance state and the power is reduced to 30% of the nominal power.



To the right is a table to clarify the operational interdependencies.

PROMS

Generic Family

FEATURES

- Largest generic PROM family available
- Reliability proven nichrome fuzes (qualified for MIL-M-38510)
- Drop in compatible ROMs
- PNP inputs for low input current
- Compatible pin configurations for upward expansion
- 4-bit-wide and 8-bit-wide for byte oriented applications
- High speed for microprogrammed applications
- Other applications include:
  - Microprocessor program store
  - Look up table
  - Character generator
  - Random logic
  - Code converter

DESCRIPTION

The 53/6300-series generic PROM family offers the widest selection of sizes and organizations available in the industry. The 4-bit-wide PROMs range from 256x4 to 1024x4 and feature upward/downward pin out compatibility in the space saving 16 and 18 pin packages. The 8-bit-wide PROMs range from 32x8 to 1024x8 in a wide selection of package sizes. All PROMs have the same programming specifications allowing a single generic programmer.

The family features low input current PNP inputs, full Schottky clamping and Three-state and open collector outputs. The nichrome fuzes store a logical high and are programmed to the low state.

The 63 series is specified for operation over the commercial temperature and voltage range. The 53 series is specified for the military ranges.

ROMS

Generic Family

FEATURES

- Largest generic ROM family available
- PNP inputs for low input current
- Compatible pin configurations for upward expansion
- 4-bit-wide and 8-bit-wide for byte oriented applications
- High speed for microprogrammed applications
- Other applications include:
  - Microprocessor program store
  - Look up table
  - Character generator
  - Random logic
  - Code convertor

DESCRIPTION

The 52/6200-series generic ROM family offers the widest selection of sizes and organizations available in the industry. The 4-bit-wide ROMs range from 256x4 to 1024x4 and feature upward/downward pinout compatibility in the space saving 16 and 18 pin packages. The 8-bit-wide ROMs range from 32x8 to 2048x8 in a wide selection of package sizes.

The family features low input current PNP inputs, full Schottky clamping and three-state and open collector outputs.

The 62 series is specified for operation over the commercial temperature and voltage range. The 52 series is specified for the military ranges.

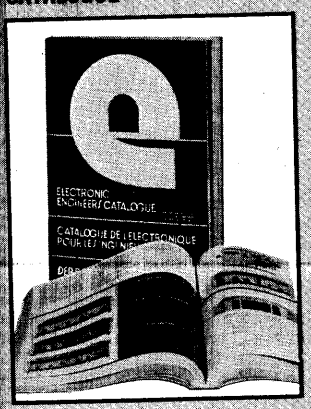
WE KNOW OUR STUFF



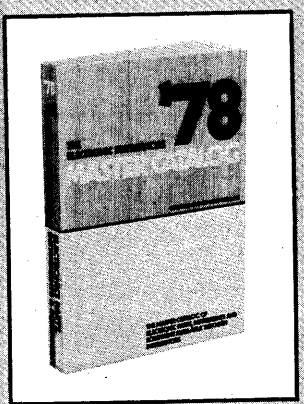
40 YEARS OF EXPERIENCE IN CATALOGING, 20 EDITIONS OF [redacted]

eem/ELECTRONIC ENGINEERS MASTER CATALOG —

The "blue-ribbon" catalog/directory that has become "the standard of the industry" for electronic engineers, buyers and specifiers.

ELECTRONIC ENGINEERS CATALOGUE

The new catalogue/directory of electronic products available to and from Western Europe and the United Kingdom. Designed especially for the European electronics engineer.



eem FILE SYSTEM —

The only filing system designed specially for the electronics engineer. Instant retrieval and organization of data sheets and catalogs.

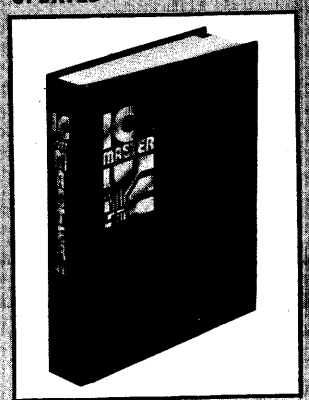
UTP CUSTOM CATALOGS —

The Cadillac of individualized catalogs for the electronic parts distributor, featuring solely his lines and services.

ELECTRONIC DISTRIBUTORS MASTER CATALOG —

(Formerly O-T-S Catalog) The only national catalog designed exclusively for distributors and their customers featuring electronic parts, instruments and equipment.

ELECTRONIC PRODUCTS MAGAZINE —



The products magazine . . . A 100% product-oriented magazine including hundreds of new products and special features every month.

UNITED COST AND PRICING SERVICES —

The electronic distributors' proven method of being up to the minute on his cost and selling prices.

IC MASTER AND THE UPDATES —

The only complete single-source directory including all IC devices manufactured in the United States. Updated three times yearly with accumulative supplements.

United Technical Publications, Inc., Div. of Cox Broadcasting Corp., 645 Stewart Ave., Garden City, N.Y. 11530/(516) 222-2500 TWX-510/222-1673

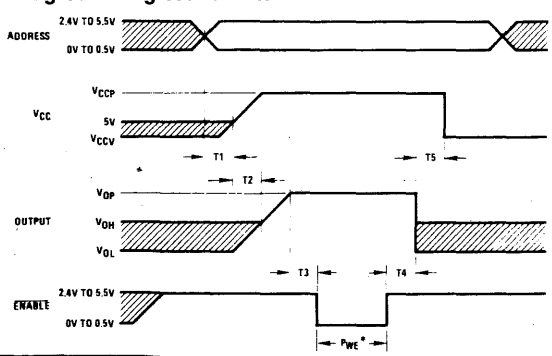
PROM programming procedure

These parts are shipped from the factory with all fuses intact. As a result, the outputs will be low (logical "0") for all addresses. In order to generate a high level on the outputs, the part must be programmed. Information on available programming equipment may be obtained from National. However, if it is desired to build your own programmer, the following conditions must be observed.



1. Programming should be attempted only at temperatures between 15°C and 30°C.
2. Addresses and chip enable pins must be driven from normal TTL logic levels during both programming and verification.
3. Programming will occur at a selected address when V_{CC} is held at 10.5V, the appropriate output is held at 10.5V and the chip is subsequently enabled. To achieve these conditions in the appropriate sequence, the following procedure must be followed:
   a) Select the desired word by applying a high or low level to the appropriate address inputs. Disable the chip by applying a high level to one or both enable inputs.
   b) Increase V_{CC} to 10.5V ±0.5V with the rate of increase being between 1.0 and 10.0V/μs. Since V_{CC} supplies the current to program the fuse as well as the I_{CC} of the device at programming voltage, it must be capable of supplying 400 mA at 11.0V.
   c) Select the output where a high level is desired by raising that output voltage to 10.5V ±0.5V. Limit the rate of increase to a value between 1.0 and 10.0V/μs. This voltage change may occur simultaneously with the increase in V_{CC} but must not precede it. It is critical that only one output at a time be programmed since the internal circuits can only supply programming current to one bit at a time. Outputs not being programmed must be left open or tied to a high impedance source of at least 20 kΩ. (Remember that the outputs of the device are still disabled at this time because the chip enables are high.)
   d) Enable the device by taking both chip enables to a low level. This is done with a pulse of 10μs. The 10μs duration refers to the time that the circuit is enabled. Normal input levels are used and rise and fall times are not critical.
   e) Verify that the bit has been programmed by first removing the programming voltage from the output and then reducing V_{CC} to 4.0V ±0.2V. Verification at a V_{CC} level of 4.0V will guarantee proper output states over the V_{CC} and temperature range of the programmed part. The chip must be enabled to sense the state of the outputs. During verification, the loading of the output must be within specified I_{OL} and I_{OH} limits. Steps b, c and d must be repeated 10 times or until verification that the bit has programmed.
   f) Following verification, apply five additional programming pulses to the bit being programmed. The programming procedure is now complete for the selected bit.
   g) Repeat steps a through f for each bit to be programmed to a high level. If the procedure is performed on an automatic programmer, the duty cycle of V_{CC} at programming voltage must be limited to a maximum of 25%. This is necessary to minimize chip junction temperatures. After all selected bits are programmed, the entire contents of the memory should be verified.

Note: Since only an enabled chip is programmed, it is possible to program these parts at the board level if all programming parameters are complied with.

Programming Parameters Do not test or you may program the device.

PARAMETERS		CONDITIONS	MIN	RECOMMENDED VALUE	MAX	UNITS
V_{CCP}	Required V_{CC} for Programming		10.0	10.5	11.0	V
I_{CCP}	I_{CC} During Programming	V_{CC} = 11V			400	mA
V_{OP}	Required Output Voltage for Programming		10.0	10.5	11.0	V
I_{OP}	Output Current while Programming	V_{OUT} = 11V			20	mA
t_{RR}	Rate of Voltage Change of V_{CC} or Output		1.0		10.0	V/μs
P_{WE}	Programming Pulse Width (Enabled)		9	10	11	μs
V_{CCV}	Required V_{CC} for Verification		3.8	4.0	4.2	V
M_{DC}	Maximum Duty Cycle for V_{CC} at V_{CCP}			25	25	%

Programming Waveforms

T1 = 100 ns min
T2 = 5μs min (T2 may be ≥ 0 if V_{CCP} rises at the same rate or faster than V_{OP})
T3 = 100 ns min
T4 = 100 ns min
T5 = 100 ns min

*P_{WE} is repeated for 5 additional pulses after verification of V_{OH} indicates a bit has programmed

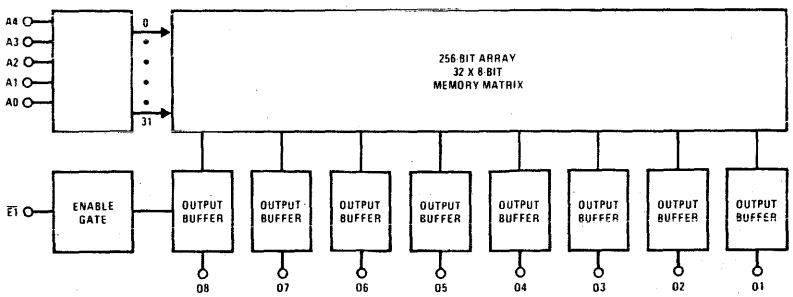
Preliminary

DM54S188/DM74S188 open-collector 256-bit PROM
DM54S288/DM74S288 TRI-STATE® 256-bit PROM

general description

These Schottky PROM memories are organized in the popular 32 words by 8 bits configuration. A memory enable input is provided to control the output states. When the enable input is in the low state, the outputs present the contents of the selected word.

If the enable input is raised to a high level, it causes all 8 outputs to go to the "OFF" or high impedance state. The memories are available in both open-collector and TRI-STATE® versions and are available as ROM's as well as PROM's.



PROM's are shipped from the factory with lows in all locations. A high may be programmed into any selected location by following the programming instructions. Once programmed, it is impossible to go back to a low.

features

- Advanced titanium-tungsten (Ti-W) fuses
- Schottky-clamped for high speed
  Address access—30 ns max
  Enable access—20 ns max
- PNP inputs reduce input loading
- All dc and ac parameters guaranteed over temperature
- Low voltage TRI-SAFE™ programming
- Board level programming

Note 1: Absolute maximum ratings are those values beyond which the device may be permanently damaged. They do not mean that the device may be operated at these values.

Note 2: These limits do not apply during programming. For the programming ratings, refer to the programming instructions.

Note 3: These limits apply over the entire operating range unless stated otherwise. All typical values are for V_{CC} = 5V and T_A = 25°C.

Note 4: During I_{SC} measurement, only one output at a time should be grounded. Permanent damage may otherwise result.

Note 5: To measure V_{OH}, I_{CEX} or I_{SC} on an unprogrammed part, apply 10.5V to both A7 and A2 (pin 15 and pin 7).

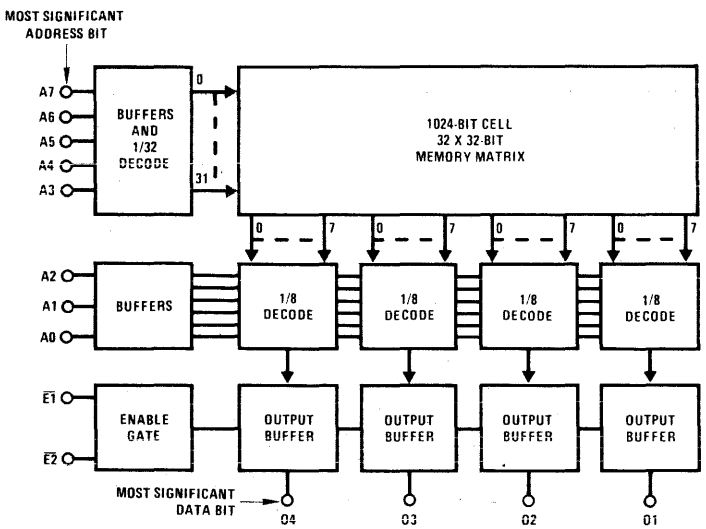
DM54S287/DM74S287 TRI-STATE® 1024-bit PROM
DM54S387/DM74S387 open-collector 1024-bit PROM

general description

These Schottky memories are organized in the popular 256 words by 4 bits configuration. Two memory enable inputs are provided to control the output states. When both enable inputs are in the low state, the outputs present the contents of the selected word.

If either or both of the enable inputs is raised to a high state, it causes all four outputs to go to the "OFF" or high impedance state. The memories are available in both open-collector and TRI-STATE versions and are available as ROM's as well as PROM's.



PROM's are shipped from the factory with lows in all locations. A high may be programmed into any selected location by following the programming instructions. Once programmed, it is impossible to go back to a low.

features

- Advanced titanium-tungsten (Ti-W) fuses
- Schottky-clamped for high speed
  Address access—50 ns max
  Enable access—25 ns max
- PNP inputs reduce input loading
- All dc and ac parameters guaranteed over temperature
- Low voltage TRI-SAFE™ programming
- Board level programming
- ROM mates are DM74S187 and DM85S97

Note 1: Absolute maximum ratings are those values beyond which the device may be permanently damaged. They do not mean that the device may be operated at these values.

Note 2: These limits do not apply during programming. For the programming ratings, refer to the programming instructions.

Note 3: These limits apply over the entire operating range unless stated otherwise. All typical values are for V_{CC} = 5V and T_A = 25°C.

Note 4: During I_{SC} measurement, only one output at a time should be grounded. Permanent damage may otherwise result.

Note 5: To measure V_{OH}, I_{CEX} or I_{SC} on an unprogrammed part, apply 10.5V to both A7 and A2 (pin 1 and pin 6).

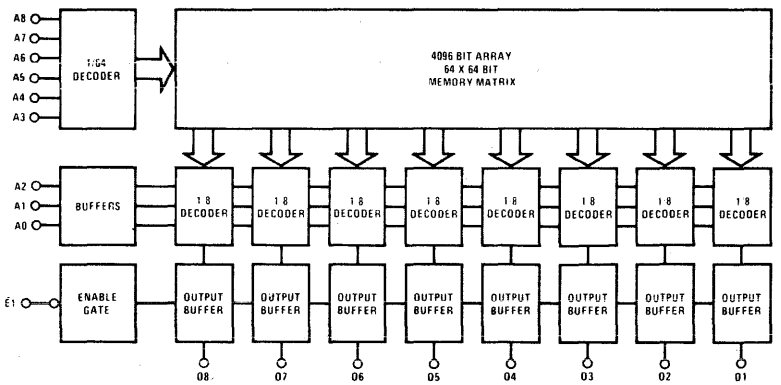
Preliminary

DM54S473/DM74S473 open-collector 4096-bit PROM
DM54S472/DM74S472 TRI-STATE® 4096-bit PROM

general description

These Schottky PROM memories are organized in the popular 512 words by 8 bits configuration. A memory enable input is provided to control the output states. When the enable input is in the low state, the outputs present the contents of the selected word.

If the enable input is raised to a high level, it causes all 8 outputs to go to the "OFF" or high impedance state. The memories are available in both open-collector and TRI-STATE versions.



PROM's are shipped from the factory with lows in all locations. A high may be programmed into any selected location by following the programming instructions. Once programmed, it is impossible to go back to a low.

features

- Advanced titanium-tungsten (Ti-W) fuses
- Schottky-clamped for high speed
  Address access—65 ns max
  Enable access—40 ns max
- PNP inputs reduce input loading
- All dc and ac parameters guaranteed over temperature
- Low voltage TRI-SAFE™ programming
- Board level programming
- High density 20-pin package

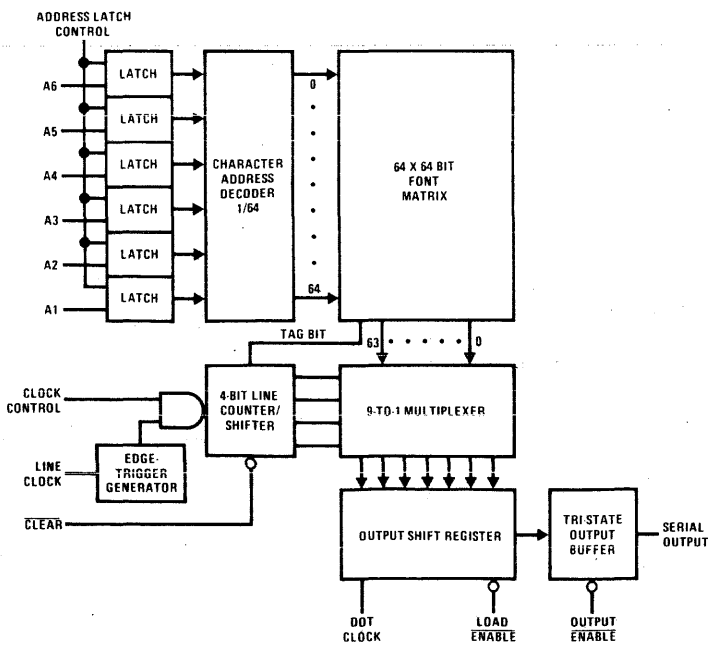
DM8678 bipolar character generator

general description

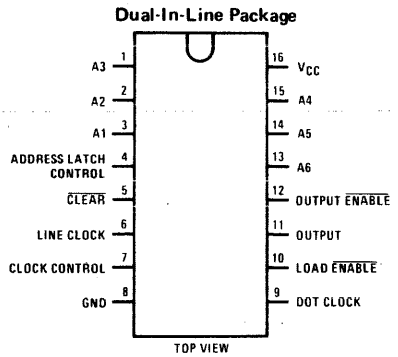
The DM8678 is a 64-character bipolar character generator with serial output, and packaged in a standard 16-pin DIP designed primarily for the CRT display marketplace. The DM8678 incorporates several CRT system level functions, as well as a 7 x 9 or 5 x 7 row scan character font. The DM8678 performs the system functions of parallel to serial shifting, character address latching, character spacing, and character line spacing which are normally done with extra packages.

Shifted characters can be generated by the on-chip subtractor.



The $\overline{\text{clear}}$ input and the load $\overline{\text{enable}}$ input are active low. load $\overline{\text{enable}}$ is synchronous with the dot clock. Both the line clock and the dot clock are positive edge-triggered. When the address latch control signal is high, the character addresses "Fall Through" the latch. And when the address latch control signal goes low, the character addresses are latched.

features



- 64-character—row scan
- 5 x 7 or 7 x 9 font
- Shifted lower case descending characters
- Serial output
- 16-pin package
- 20 MHz clock rate
- On-chip input latches
- On-chip shift register
- On-chip dot blanking
- On-chip row blanking
- TRI-STATE® output

standard test load

- Input waveforms are supplied by a pulse generator having the following characteristics: PRR = 1 MHz, Z_{OUT} = 50 Ω, $t_r < 2.5$ ns and $t_f < 2.5$ ns (between 1.0V and 2.0V).
- T_{DO} is measured with output enable at a steady low level.

X	X	L	Asynchronous clear resets counter
L	X	H	Clock inhibited
H	¬	H	No change on high-to-low clock edge

X = Don't care

definitions

A1–A6: Character address. A 6-bit code which selects 1 of the 64 characters in the font.

$\overline{\text{Clear}}$: Active low clear for mod 16 row counter, (can be used to truncate mod 16 counter).

Line Clock: Clock that advances the line counter. Advances counter on the low-to-high transition.

Clock Control: Enables line clock when high and disables line clock when low.

Load $\overline{\text{Enable}}$: Active low load command which routes data from the character ROM to the "D" inputs of the 7-bit shift register.

Dot Clock: A low-to-high transition of the dot clock loads the shift register if load $\overline{\text{enable}}$ is low or shifts data if load $\overline{\text{enable}}$ is high.

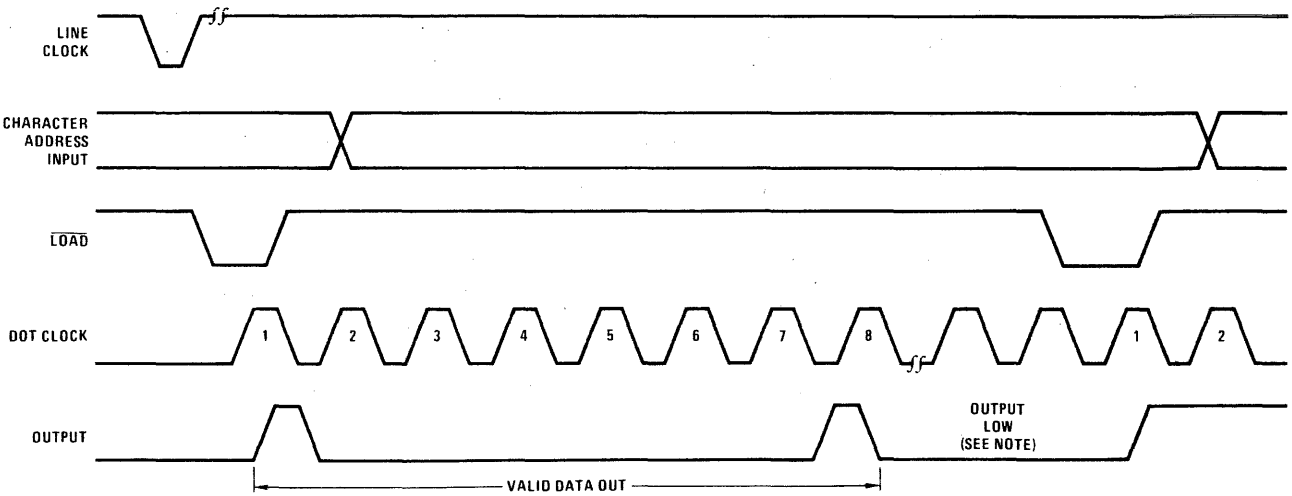
Output $\overline{\text{Enable}}$: An active low output enable. When high the output is in the Hi-Z state.

Output: A TTL TRI-STATE output buffer.

functional description

To select a character, a 6-bit binary word must be present at the address inputs A1–A6 when the address latch control is high. This address can be latched by bringing the address latch control signal low after a 40 ns set-up time. When the $\overline{\text{clear}}$ input receives a low pulse, the counter is reset to zero. The shift register can be loaded (t_{ASL} ns) after the character is addressed. Data, representing one horizontal line of the addressed character, is available at the output when the load $\overline{\text{enable}}$ input is brought low. As shown in *Figure 1*, valid data arrives serially at the output. Dot clock pulses beyond that required to shift out one line of the character will add lows to the end of character. This provides a horizontal spacing between characters.

Figure 2 shows how the counter sequences through the rows of addressed lines with the application of clock pulses at the line clock input. Any additional line clocks beyond that required to display the character will put a vertical space between characters. This spacing can be truncated by bringing the $\overline{\text{clear}}$ input low. Detailed system application infomation is contained in application note AN-167 available from National.



A two character display example is shown in *Figure 3* and a typical system timing waveform is shown in *Figure 4.*

A chip select input is provided for expansion of the character font. The various standard fonts are shown in *Figures 5, 6, 7, 8, 9 and 10.*

functional description (Continued)

Character Cycle – ROM data corresponding to one line of characters is loaded into the shift register t_{ASL} after the ROM is addressed. When load $\overline{\text{enable}}$ goes low, ROM data is allowed to be present at the D input of the shift register via the MUX. The first bit of the ROM data is transferred to the output at the next low-to-high transition of the dot clock. After load $\overline{\text{enable}}$ goes back high, the second to seventh clock pulses shift out the rest of the selected row of the addressed character. Additional clock pulses will shift out low data used for spacing.

Line Cycle – The line counter is a mod 16 counter. A low-to-high transition of the line clock advances the line counter to the next count. If, for any reason, the counts need to be truncated, a low signal at the $\overline{\text{clear}}$ input resets the counter to zero. The clock control may be used as a line clock disable. A high signal at the line clock control terminal enables the counter and a low signal disables the line clock.

Note. Output goes and stays low following the leading edge of the eighth Dot-Clock pulse until load $\overline{\text{enable}}$ is enabled again and new parallel data is loaded into the shift register.

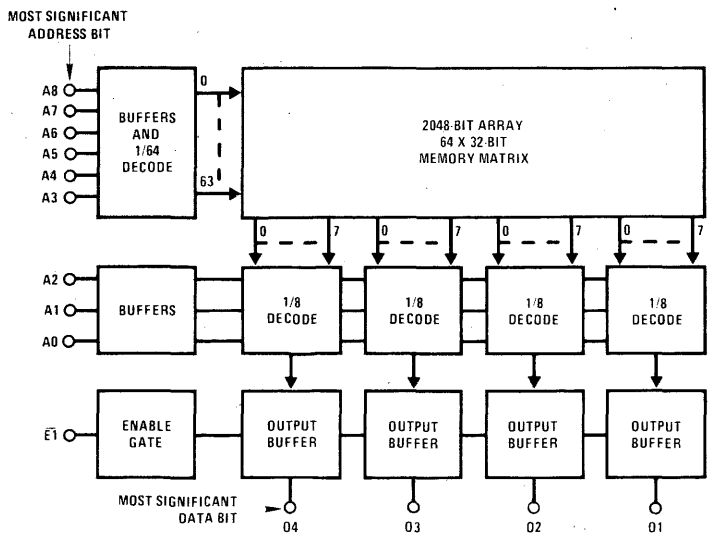
DM54S270/DM74S270 open-collector 2048-bit ROM
DM54S370/DM74S370 TRI-STATE® 2048-bit ROM

general description

These Schottky ROM memories are organized in the popular 512 words by 4 bits configuration. A memory enable input is provided to control the output states. When the enable input is in the low state, the outputs present the contents of the selected word.



If the enable input is raised to a high level, it causes all 4 outputs to go to the "OFF" or high impedance state. The memories are available in both open-collector and TRI-STATE versions and are available as PROM's as well as ROM's.

features

- Schottky-clamped for high speed
  Address access—55 ns max
  Enable access—30 ns max
- PNP inputs reduce input loading
- All dc and ac parameters guaranteed over temperature
- PROM mates are DM74S570 and DM74S571

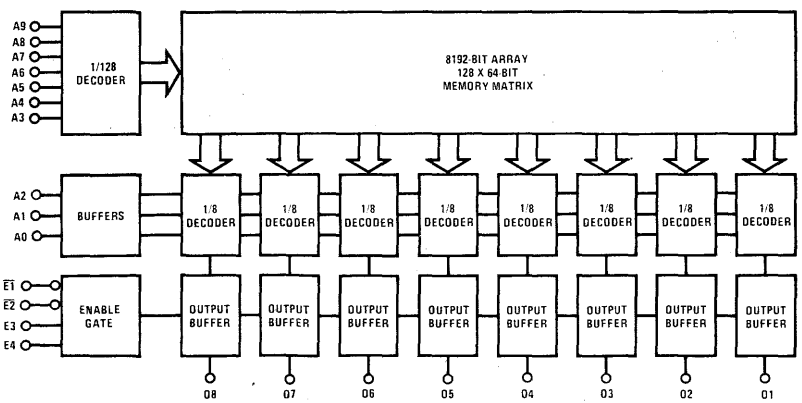
DM75S29/DM85S29 open-collector 8192-bit ROM
DM75S28/DM85S28 TRI-STATE® 8192-bit ROM

general description

These Schottky ROM memories are organized in the popular 1024 words by 8 bits configuration. Four memory enable inputs are provided to control the output states. When E1 and E2 are low and E3 and E4 are high, the output presents the contents of the selected word.



If E1 or E2 are high, or E3 or E4 are low, it causes all 8 outputs to go to the "OFF" or high impedance state. The memories are available in both open-collector and TRI-STATE versions and are available as PROM's as well as ROM's.

features

- Schottky-clamped for high speed
  Address access—70 ns max
  Enable access—45 ns max
- PNP inputs reduce input loading
- All dc and ac parameters guaranteed over temperature
- PROM mates are DM87S229 and DM87S228

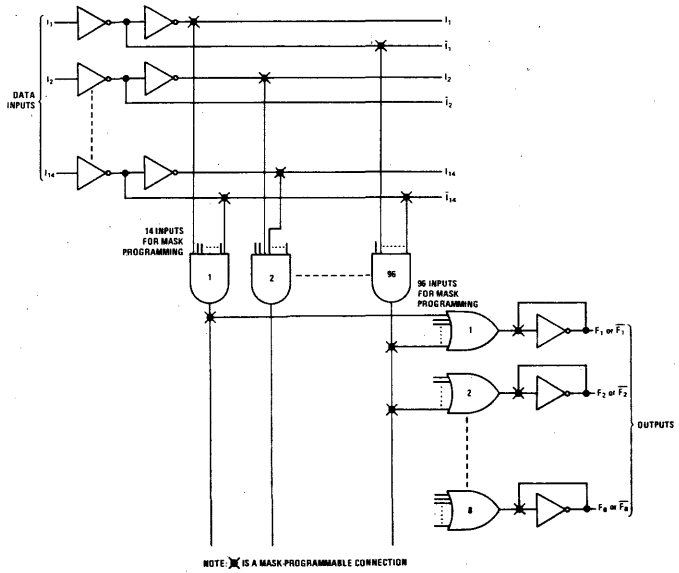
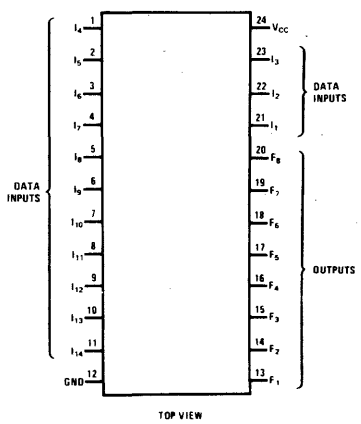
Bipolar ROMs

DM7575/DM8575, DM7576/DM8576 programmable logic array (PLA)



general description

The DM7575/DM8575 and DM7576/DM8576 are mask-programmable logic arrays designed for use in applications where random logic is required. The devices have fourteen data inputs and eight outputs. Each output provides a sum of product terms where each product term can contain any combination of 14 variables or their complements. The total number of product terms which can be provided is 96. Any product term which is repeated is counted only once. Since some functions are more easily represented in their inverted form, an option is provided to allow for either the true or complement of the function on each output. The products are particularly useful in providing control logic for digital systems. The DM7575/DM8575 has a conventional totem-pole output whereas the DM7576/DM8576 is provided with a passive pullup output. This latter configuration is useful in expanding functions by connection of outputs of different packages.



features

- A 2^{14}-by-8 (128k) bit memory would be needed to provide equivalent function
- Typical delay 90 ns
- Typical power dissipation 550 mW
- Series 54/74 compatible

Propagation Delay to a Logical "1" from Data Inputs to Outputs, t_{pd1}	V_{CC} = 5.0V, T_A = 25°C		80	150	ns

Note 1: "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. Except for "Operating Temperature Range" they are not meant to imply that the devices should be operated at these limits. The table of "Electrical Characteristics" provides conditions for actual device operation.

Note 2: Unless otherwise specified min/max limits apply across the −55°C to +125°C temperature range for the DM7575/76 and across the 0°C to 70°C range for the DM8575/76. All typicals are given for V_{CC} = 5.0V and T_A = 25°C.

Note 3: Only one output at a time should be shorted.

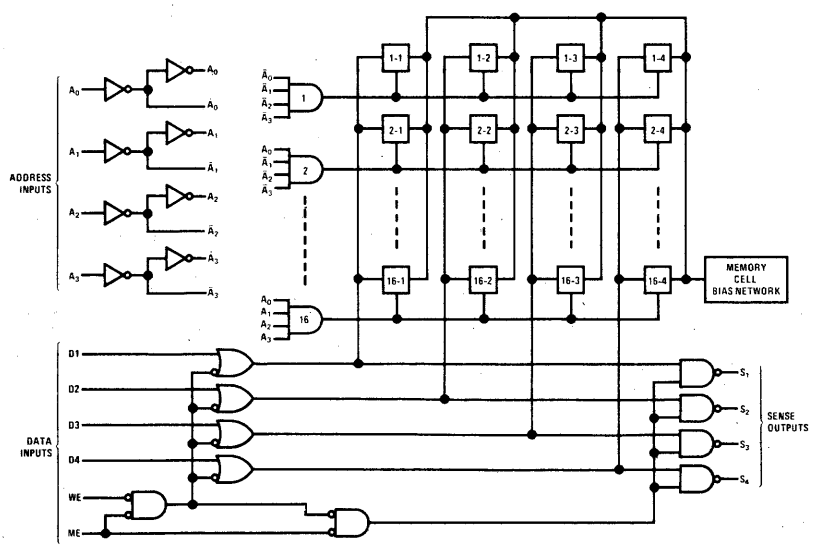
Bipolar RAMs

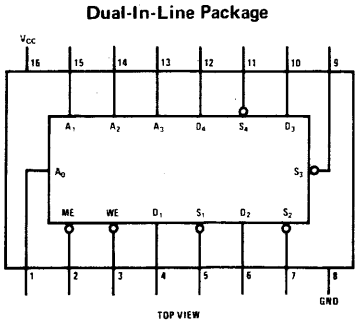
DM5489/DM7489 (SN5489/SN7489)
64-bit random access read/write memory



general description

The DM5489/DM7489 is a fully decoded 64-bit RAM organized as 16 4-bit words. The memory is addressed by applying a binary number to the four Address inputs. After addressing, information may be either written into or read from the memory. To write, both the Memory Enable and the Write Enable inputs must be in the logical "0" state. Information applied to the four Write inputs will then be written into the addressed location. To read information from the memory the Memory Enable input must be in the logical "0" state and the Write Enable input in the logical "1" state. Information will be read as the complement of what was written into the memory. When the Memory Enable input is in the logical "1" state, the outputs will go to the logical "1" state.

features



- Series 54/74 compatible
- Organized as 16 4-bit words
- Typical access from chip enable 23 ns
- Typical access 35 ns
- Typical power dissipation 400 mW
- Open collector outputs to permit "wire OR" capability
